## WHAT PRICE FOR TRANQUILITY?

The effects of tranquilizing drugs have been studied in 8 200 patients in whom anxiety was the normal chief finding. The group was limited to people of normal physical make-up and of at least average intellectual capacity who were capable of working steadily and were complaining of tension worry and associated physiological disturbances. Of these 7 500 had taken some amount of the tranquilizing drugs before they came under observation. The danger to the patient's physical health is shown by the appearance of allergic phenomena in 96 general toxic effects in 78 habituation in 72 severe liver disturbances in 31 other severe symptoms in 97 and death in 4. Two of the deaths were suicides. The danger to the patient's emotional health is shown by the finding of about 1 700 instances in which serious problems were created in essentially normal people and 827 instances in which emotional illness was aggravated. The danger to the physician results from accumulating pressure on the medical profession from the people who produce and those who demand these drugs. There is fourthly a grave danger to society in the idea that tensions should be reduced by techniques of relaxation and administration of drugs rather than by the constructive effort required for satisfying needs and removing dangers. The physician must inform himself well about these drugs and reorient his own thinking about their indications and limitations.

in *Journal of the American Medical Association*, p 422 Feb 9 1957

Assigned to the installation having primary responsibility for the dental care of antiaircraft artillery personnel in each of the major defense areas in the Second Army, it is planned to have the units visit each site on a regularly scheduled itinerary. Visits of 10 days to 2 week duration will enable the dental surgeon to conduct a dental survey at the site and apportion his time and efforts accordingly. Cases requiring extensive or complicated treatment beyond the capabilities of the mobile facility will be referred to a fixed installation for such care. Depending on the number of sites to be served in a particular area, the results of dental surveys, and other factors, it is estimated that return visits can be made on an average of every 3 or 4 months.

The availability of these mobile clinics satisfies a long standing need and enables the Army Dental Corps to better fulfill its role and mission as a part of the Army Medical Service.

---

### THOROUGHNESS

"No quality in the practicing physician is more important than thoroughness. With it a clear mind can become great; a mediocre one expert. Without thoroughness inexcusable errors are certain to occur during the professional lifetime of a doctor. Painstaking thoroughness in the daily routine of work is a distinguishing characteristic of the scientist. It is a habit of mind difficult for some to acquire, easy for others—absolutely essential for the successful care of medical patients."

# CASE REPORTS—TORSION APPENDIX TESTIS

597

the testis. An exception to this is the one case reported by Vermeulen and Hagerty<sup>1</sup> in which the patient, a 10 year old boy, was acutely ill and tenderness precluded careful palpation of the testis until after he was anesthetized, at which time a movable mass attached to the upper pole of the testis was palpable.

The treatment of choice is surgical excision of the twisted appendix. Seidel<sup>2</sup> reported one case which responded to conservative therapy, but it is generally concluded that surgery shortens the period of morbidity.

I have treated three patients diagnosed as having torsion of the appendix testis. Two were treated conservatively and the diagnosis was consequently confirmed by surgery in only one case.

## CASE REPORTS

Case 1. A 10 year-old boy was seen in the urology clinic at this hospital on 13 August 1956 with a history of having developed sudden pain in the right scrotum and inguinal region one week prior to this time. Since then the pain had been intermittent, aggravated by walking and apparently relieved by sitting or lying still. There were no systemic symptoms and his appetite was good. There had been no contact with mumps. Urinary symptoms were denied. There was no previous history of genitourinary complaints except that both testes tended to retract into the inguinal canal though they would descend to the scrotum when he sat in a warm tub.

Examination revealed an obese male in no apparent distress. Adduction of the right thigh was noted while walking but no discomfort was noted while sitting or lying still. Temperature was 99.4°F orally. Physical examination was negative except for marked edema and erythema of the right hemiscrotum, exquisite tenderness over the scrotum and right inguinal region and the presence of both testes at a level just below the external inguinal ring. Because of the tenderness neither testis could be pushed into the scrotum. The white blood cell count was 11,000 per  $\mu$ l with a differential count of 70 per cent neutrophils, 25 per cent lymphocytes, 1 per cent monocytes and 4 per cent eosinophils.

The patient was treated conservatively for one day with no appreciable diminution of symptoms and consequently surgical exploration of the right testis was performed with a preoperative diagnosis of torsion of the spermatic cord. The tunica vaginalis contained approximately 10 ml of clear yellow fluid. The testis and epididymis appeared normal but attached to the superior pole of the testis immediately anterior to the globus major of the epididymis was a red soft structure 1 cm in diameter. This was apparently twisted counterclockwise. The testis and tunica vaginalis were excised, the incision closed and the patient discharged from the hospital on

## CASE REPORTS

### TORSION OF THE APPENDIX TESTIS

HERBERT S. FRIEDMAN Captain USAF (MC)

THE most consistent vestigial organs found on the testes are the appendix testis and epididymis derived respectively from the cranial ends of the Mullerian duct and mesonephric collecting tubules. The frequency with which these structures occur are demonstrated by the findings of Sundarasivarao<sup>1</sup> who reported that on 152 testes examined 122 were found to have an appendix testis and 35 an appendix epididymis. Only 21 specimens had neither and only 6 subjects had neither vestige bilaterally.

The only pathologic condition affecting these structures primarily is torsion. This was described by Orhredanne<sup>2</sup> in 1913 and since then has been shown to be a not uncommon occurrence as evidenced by the number of reported cases appearing in the medical literature. Scott<sup>3</sup> collected 85 reported cases including one of his own in 1940. Seidel and Leav<sup>4</sup> found 14 other cases and added 6 of his own to bring the total to 107. Since then there have been numerous case reports appearing in the American medical literature.<sup>5-7</sup>

The cause of the torsion is unknown and the condition has occurred in undescended as well as in descended testes with no known increase in frequency in the former. It has been found in a 4<sup>1</sup>/<sub>2</sub> month old infant as well as in a 39-year old man. The age group of most common occurrence is 10 to 14 years. The ordinary clinical picture is acute onset of pain in one testis sometimes associated with a sudden movement. Swelling of the testis on the affected side along with edema and erythema of the overlying scrotal skin soon occurs. There are very few systemic symptoms and little if any fever. Palpation of the testis where this is permissible demonstrates a tender nodule either attached to or immediately anterior to the globus major of the epididymis. This may be differentiated from acute epididymitis by the acute onset absence of the testis. Torsion of the findings upon examination of the prostate and tenderness at the upper rather than the lower pole of the testis. Torsion of the spermatic cord may be differentiated from torsion of the appendix testis by the fact that in the latter the symptoms are less severe and there is a tender nodule at the upper pole of

From U. S. Air Force Hospital, Lowry Air Force Base, Colo.

day. When seen one week postoperatively the incision was well healed and no edema of the testis was present.

#### Pathologist's Report

The specimen submitted consisted of a rounded piece of tissue measuring 1 by 1 by 0.3 cm. The tissue was smooth and soft. The color varied from dark red to dark blue. Cut sections presented a smooth glistening dark red slightly bulging surface.

The sections showed a piece of loose connective tissue rich in blood vessels and lined by one layer of columnar ciliated epithelium.

The connective tissue was diffusely infiltrated by inflammatory cells predominantly polymorphonuclear like leukocytes. The blood vessels were distended. Areas of extravasated blood were present within the stroma. There were no epithelial inclusions in the stroma of the specimen. No thrombosed blood vessels and no areas of necrosis were present (figs 1 and 2).

Figure 1. Section through entire appendix testis showing severe congestion and hemorrhage in the loose connective tissue stroma. Epithelial cells surround the specimen. There are no epithelial cell inclusions in the stroma. (48-mm Microtesssar hematoxylin-eosin stain.)

Diagnosis: Appendix testis inflammation, acute hyperemia, hemorrhage.

Figure 2 Epithelial lining consists of tall columnar ciliated cells ( $\times 675$  hematoxylin eosin stain)

**Case 2.** A 24 year-old man was admitted to the hospital on 29 May 1956 with the complaint of pain at the superior pole of the right testis for three days. He had previously been told that he had a small cyst on the upper pole of the right testis which had always been asymptomatic. The structure was now quite tender though no other abnormal physical findings were present. He was treated conservatively and discharged asymptomatic on 31 May.

**Case 3.** A 24 year-old airman was seen in the urology outpatient clinic with the complaint of pain in the right testis which had occurred suddenly two days before. The day following the onset of the pain he had taken several APC tablets which afforded no relief. There was no history of trauma, and no previous similar pains had occurred. He had no urinary symptoms or any systemic symptoms. Examination revealed mild tenderness of the right testis. The epididymis was normal. There was an exquisitely tender nodule about 1 cm in diameter attached to the superior pole of the right testis just anterior to the head of the epididymis. He was treated with ice packs and scrotal support and became asymptomatic in two days.

#### COMMENTS

The first of the patients presented was proved by surgical exploration to have torsion of the appendix testis. Though the preoperative diagnosis was torsion of the spermatic cord, the

day. When seen one

# Pulmonary Amebiasis

## Combined Resection and Medical Therapy

MILAN L. BRANDON, *Lieutenant MC USA*

II LIONARD JONES, *Captain MC US*

HORACE D. WARDEN, *Captain MC USA*

AS a result of modern therapy the morbidity of amebiasis has been significantly decreased. There are many antibiotics for intestinal amebiasis, chloroquine phosphate, quinacrine hydrochloride, and emetine hydrochloride are useful for hepatic amebiasis, and antibiotics are particularly useful for secondary bacterial invasion. There is little indication, however, of significant progress in lowering the mortality rate of amebiasis.<sup>1</sup> The rapid strides in chemotherapy have tended to obscure the indications for surgery, especially in hepatic and pleuropulmonary amebiasis. Some cases are resistant to drug therapy and, in addition to simple drainage, there are other surgical procedures which are now available and applicable in certain instances.

The diagnosis of pulmonary amebiasis is frequently difficult or is often unsuspected.<sup>2</sup> Due to the increasing trend to resect suppurative pulmonary lesions, the diagnosis of amebiasis is established occasionally only after thoracotomy.<sup>3</sup> The following is a report of a case of pulmonary amebiasis, diagnosed at surgery and treated by pulmonary resection and drug therapy.

### CASE REPORT

A 36-year old Negro veteran was admitted to this hospital 26 October 1956 with complaints of cough and right posterolateral pleuritic chest pain of two months' duration. He had increased fatigability, anorexia and had lost 40 pounds. Initially the cough produced small amounts of clear mucoid sputum, but during the second month there were frequent paroxysms of cough which produced blood streaked sputum. He had felt feverish but had no chills. He had no gastro intestinal complaints.

Past history revealed that he had lived in Massachusetts, Louisiana and Georgia, had traveled throughout the world from 1943 through 1946. He was given antimalarial therapy in the Philippines in 1944. He had smoked from 10 to 15 cigarettes per day for 15 years. Family history and systemic review were noncontributory.

On examination the patient appeared emaciated and he coughed frequently. His blood pressure was 120/70 mm Hg pulse rate 100 per minute respiration 18 and temperature 100.4°F. There was an irregular enlargement of the right first costochondral junction. He had clubbing of the fingers. The right lung was dull to percussion at the base with diminished breath sound, and tactile fremitus but with no other definite signs of fluid. Medium to coarse moist inspiratory rales were present throughout the right lung. No abnormalities of the abdomen were noticed on examination.

Examination of the blood showed an initial hemoglobin of 10.7 grams per 100 ml hematocrit 35 ml per 100 ml white blood cell count 24,600 per  $\mu$ l with moderate shift to the left normal electrolytes negative sickle cell preparation and the serologic tests for syphilis were negative. Sulfobromophthalein sodium retention was 15 per cent in 45 minutes. His urine was normal. An initial sputum culture was positive for *Diplococcus pneumoniae* which was sensitive to the antibiotics being used in his treatment. Sputum smears and cultures and urine cultures for acid fast bacilli were negative. The tuberculin skin test was positive histoplasmin skin test was 4 plus positive and the coccidioidin skin test was negative.

On admission roentgenograms of the chest showed a density in the right apex and a rounded fairly homogenous soft tissue density without cavitation occupying the major part of the right lower lobe as well as pleural thickening and/or fluid in the anterior costophrenic sinus. Plain roentgenograms of the abdomen showed no abnormalities. Treatment was begun immediately with 250 mg oxytetracycline four times daily. Fever persisted at 100° to 101°F and penicillin and streptomycin sulfate were started on the 5th hospital day. Rales persisted at the right lung base and tenderness and fullness were noted at the right costal margin but the liver edge could not be palpated or percussed. Roentgenograms of the chest on the 7th day were unchanged. Fever subsided on the 10th day but only for a few days. Cough was nonproductive persistent and associated with pleuritic pain. Roentgenograms of the spine, ribs and skull showed no evidence of metastatic disease. Tomograms of the chest on the 12th day showed a large lymph node in the region of the bifurcation of the right main stem bronchus and a 9- by 8-cm soft tissue density in the right base with some constriction and irregularity of the right inferior bronchus. Bronchoscopy on the 14th day showed some injection of the mucosa of the right lower lobe bronchus with moderately thick mucoid secretions loaded with coccoid bacteria. Papanicolaou smear was negative. Complaints and findings persisted. Roentgenograms of the chest on the 25th day showed the density in the right base to have diminished slightly in extent and a faint circular area of radiolucency indicating either resolution of consolidation or possible cavitory change.

On the 26th day exploratory thoracotomy revealed acute and chronic inflammation in the right lower lobe including many old and recent pleural adhesions and a large thick walled abscess involving the

basilar segments of the right lower lobe which communicated in the shape of an hourglass through a 3 mm defect in the diaphragm with a 3 cm subphrenic abscess cavity containing purulent material. An old granulomatous infiltrate in the apical segment of the upper lobe was left intact. Resection of the right lower lobe basilar segments, and external drainage was accomplished. Before the patient left the operating room, histologic examination of a smear from the abscess wall stained with MIF (Merthiolate iodine formaldehyde)<sup>1</sup> revealed trophozoites of *Entamoeba histolytica* (fig. 1). Histologic examination of the abscess wall after formalin preparation showed necrotic lung tissue containing *E. histolytica* trophozoites. Cultures and smears for acid fast bacilli, fungi, and bacteria were all negative.

Figure 1 Smear from wall of lung abscess revealed trophozoites of *Entamoeba histolytica* and established the diagnosis of amebiasis (MIF stain)

Chloroquine phosphate (1.0 gram daily for 2 days, then 0.5 grams daily for 18 days) and emetine (0.06 gram daily for 6 days) were started without delay. Serial electrocardiograms taken while the patient was receiving emetine were all normal. Following the course of emetine, 0.21 gram of Diadoquin (brand of diodohydroxyquin) three times a day was given for 18 days. Chloroquine was restarted on the 45th day, 1 gram daily for 2 days, then 0.5 gram daily for 10 days. Oxytetracycline was discontinued and the drainage tubes were removed on the 33d day, or 1 week after surgery, when he was afebrile. Peni-

cillin and streptomycin sulfate were discontinued 3 weeks later. He remained afebrile and essentially asymptomatic. Roentgenograms of the chest showed some postoperative reaction in the right hemithorax which cleared gradually after removal of the drainage tubes.

Proctoscopy on the 55th day or 5th week postoperatively revealed hyperemia, petechiae and multiple small 2 to 3 mm ulcerations of the sigmoid colon and amebic cysts were identified on smear stained with MIF (fig 2). No abnormalities were seen on examination with a barium enema. A third chloroquine course was administered and 0.25 gram of carbarsone twice daily for 10 days was added. Small ulcerations of the sigmoid were still present but appeared to be granulating in well when the drugs were discontinued. Vioform (brand of iodochlor hydroxyquin) 250 mg three times daily for 14 days was then administered. Subsequent examinations and studies were normal and there was only residual scarring evident in the roentgenograms of the chest.

Figure 2 Amebic cysts identified in smear from ulceration of sigmoid colon. (MIF stain)

### DISCUSSION

Amebic pleuropulmonary involvement is secondary to amebiasis elsewhere and is generally the result of direct extension of hepatic amebiasis through the diaphragm into the lung, bronchus or pleura, resulting in lung abscess, bronchopleural fistula, or empyema. In a recent report of 148 fatal cases of amebiasis from the Armed Forces Institute of Pathology, amebic liver abscess was present in 61 per cent of the patients and 41 abscesses were ruptured.<sup>1</sup> Of the abscesses that ruptured 22 extended into the lung. In 18 patients with liver abscess there were no detectable intestinal lesions in 3 of these there was extension

June 1957)

# CASE REPORTS—PULMONARY AMEBIASIS

905

into the lung Amebiasis was correctly diagnosed ante mortem in only one third of all the cases, and liver abscesses were missed clinically in one half of 90 patients in whom the lesion was present

It, therefore, was not surprising to have met such diagnostic difficulties in our patient, the most disturbing of which were (1) initial positive cultures of *D. pneumoniae*, (2) roentgenographic evidence of right apical lung density, (3) positive reactions to tuberculin and histoplasmin skin tests, (4) lack of clinical or roentgenographic signs of right pleural effusion, (5) no evidence of cavitation in roentgenograms of the chest, and only the barest suspicion of this on tomograms, (6) lack of typical appearance of lesion and abscess contents at operation, and (7) absence of gastro intestinal complaints. Thus, it was important to consider an amebic origin in pleuropulmonary suppuration and to search immediately for amebias at thoracotomy, in order to institute prompt antiamebic therapy, without waiting for the processing of sections

In 1943, Ochsner and DeBakey<sup>4</sup> concluded that surgery offered little in the treatment of pleuropulmonary amebiasis, because the mortality of open drainage alone was 46.2 per cent, of open drainage plus emetine, 16.6 per cent, and with emetine alone it was only 5.4 per cent in their series. Advances in chemotherapy and improvement in surgical technic have made operative procedures other than simple external drainage practical and applicable in certain instances. Shaw<sup>5</sup> reported a case of chronic amebic pleuritis and pneumonitis in a patient whom he operated upon electively because of lack of response of the infection to antiamebic drugs and thoracenteses. He stated that when pleuropulmonary complications of amebic hepatic abscess do occur, surgical intervention may be necessary to (1) eliminate a persistent fistulous channel between the bile duct system and bronchus, (2) remove damaged pulmonary tissue that produces a continued moribund state, and (3) decorticate the lung and diaphragm in empyema when the lung cannot be re-expanded by repeated aspirations

In suspected pleuropulmonary complications of amebic hepatic abscess, Ochsner and DeBakey<sup>4</sup> pointed out that the prognosis is not as good in those with a small or absent communication between a bronchus and an area of marked lung reaction as in those with a large communication which permits rapid evacuation. When there is no communication with a bronchus the cough will tend to be nonproductive and amebas will be absent in the sputum. The diagnosis will be difficult to establish and the course will simulate a primary bacterial or fungus infection, or a malignant neoplasm with secondary infection. In such a case the diagnosis may be established only at thoracotomy, as in our patient. It

is the third patient in whom pulmonary amebiasis was successfully treated by pulmonary resection combined with antibiotics, chloroquine, and emetine. It is noteworthy that no failures with such combined treatment have been reported in the available literature. It would therefore, appear that this type of surgical procedure together with vigorous antamebic drug therapy might reasonably be expected to improve the prognosis of advanced pulmonary amebiasis.

### SUMMARY

An unusual case of amebic lung abscess is reported, which (1) presented exceptionally difficult diagnostic features and (2) was treated successfully with segmental resection combined with emetine, three courses of chloroquine and other amebicides, as well as antibiotics. This is the third reported case of a patient with pulmonary amebiasis treated in this manner. By removing the products of infection as completely as possible, it is our belief that this form of surgical intervention combined with vigorous multiple drug therapy will further lower morbidity and mortality in advanced pulmonary amebiasis.

## Fracture Following Corticotropin Therapy

WALLIS L. CRADDOCK Lieutenant Colonel MC USAR

ALL of the many available preparations of corticosteroids and corticotropin (ACTH) are capable of causing complications involving bone. Apparently none is safer than the others. The first report of pathologic changes in bone following the use of these drugs was in 1950.<sup>1</sup> In the two cases described, osteoporosis of rheumatoid arthritis was a contributory factor in producing fractures. In one of these cases, a 70 year old woman suffered fracture of the right femoral neck with pronounced displacement after 34 days of cortisone therapy. Extreme osteoporosis at the fracture site was noted when open surgical reduction was attempted.

Demnrtini, Grokoest, and Rngnn<sup>2</sup> in 1952 reported a series of five patients with rheumatoid arthritis, all of whom were predisposed to osteoporosis prior to hormone treatment. Following therapy with cortisone they developed compression fractures of the lower dorsal and lumbar spines. These patients were female, four of them postmenopausal, and their physical activity was limited. Subsequent reports have indicated that intensive and prolonged use of the hormones is a prerequisite for osteoporotic changes, but that these changes are not a rare complication of such therapy.<sup>3,4,5</sup>

Osteoporosis with vertebral fractures is a clinical feature of Cushing's syndrome in over 80 per cent of cases.<sup>6,7</sup> Becks and associates<sup>8</sup> demonstrated that ACTH tends to retard endochondrogenesis and osteogenesis in normal rats, accounting for the irregular arrangement of bony trabeculae, as well as irregular cartilage columns in the erosion zones. Blunt and co-workers<sup>9,10</sup> studied the effect of cortisone on the responses of the connective tissues to trauma. The reparative process remained sluggish after the fourth postfracture day, with relatively little tissue differentiation, and there was only minimal healing between the ends of the fractured bone. The intercellular matrix appeared quite irregular in structure. Fibroblasts appeared abnormal with bizarre arrangements of nuclear chromatin.

From Outpatient Clinic Veterans Administration Regional Office 1750 S Redwood Rd Salt Lake City Utah

It was concluded that (1) the blood supply might be inadequate due to dearth of new blood vessels with insufficient nutrition of tissue or that (2) through the low now blood vessels which did penetrate the area, a material perhaps cortisone itself was transported which inhibited growth and development of connective tissue. At any rate, the primary disturbance is lack of bone matrix formation due to deficiency in protein metabolism. The osteoporosis produced by cortisone and ACTH therapy should not be confused with osteomalacia, where the primary disturbance is demineralization of bone or with parathyroid disease, where the disturbance is destruction of bone.

More recently, vertebral fractures after use of corticosteroids have been reported in younger males. One interesting report describes the occurrence of fractures of the spine in a 9 year old boy being treated for Still's disease.

To ensure earliest possible detection of osteoporosis, urinary calcium excretion studies should be performed serially on patients who are receiving corticosteroids and ACTH. A value above 150 mg per day points to a negative calcium balance. Such a calcium excretion may indicate loss of bone mass. Periodic roentgenograms of the spine also serve as guides in predicting vertebral fractures.

Post mortem findings in cases of hormone induced osteoporosis with pathologic fractures have been well documented. Although the osteoporotic changes have a predilection for the lumbodorsal spine and pelvic bones similar changes have been observed in the knee ankle, and subtalar joints. In addition to the marked bone deformity the overlying cartilage may deteriorate rapidly and prominent secondary hypertrophic changes may appear about the joint margins. Microscopic examination of the softened vertebrae reveals few bony trabeculae, no evidence of osteoid activity and little osteoblastic or osteoclastic activity. Fractures of ribs are repaired by large quantities of poorly ossified cartilage.

It has been suggested that continuous action of the depository type of ACTH (ACTH gel) is responsible for changes in bone, whereas when the drug is administered intermittently (intravenously) osteoporosis does not occur. The assumption has been made that with the older types of treatment the adrenal gland had some chance to recover its function between injections.

The bone damage caused by cortisone and ACTH appears to be irreversible despite the use of estrogens and testosterone. Once this condition appears only conservative measures of treatment are of any help. To forestall the development of aseptic necrosis or Charcot like changes in weight bearing joints "patients can be warned to avoid weight bearing as much as possible to use crutches and canes to support already damaged joints, and thus to extend the usefulness of joints."

Discontinuation of maintenance therapy presents difficulties, in that symptoms of cortisone withdrawal and an exacerbation of the underlying disease may occur.

The following case report illustrates the problem encountered during maintenance ACTH therapy even when none of the contributory conditions causing pathologic changes in bone are present prior to prolonged hormone therapy.

### CASF REPORT

A 43 year old white male veteran had been treated for neurodermatitis since 1945 otherwise he was in excellent health. All attempts to control this patient's condition failed until October 1952 when startling improvement occurred three to four days after intravenous infusions of ACTH were begun. Since 1953 (for over three years) he had been taking ACTH gel. He had always been able to get the drug despite frequent warnings of possible complications. There were transient features resembling a Cushing syndrome at times but these cleared rapidly when ACTH was discontinued for a short time. It was impossible to determine the total amount of corticotropin the patient had taken during the period of four years. Whenever he was hospitalized and the drug withdrawn reactions resembling those described as the "cortisone withdrawal syndrome" were noted.

During hospitalization in August 1954 roentgenograms of the spine and pelvis showed no abnormalities. He avoided further hospitalization until April 1956 because physicians were reluctant to continue the ACTH. Physical findings were within normal limits, despite the fact that the patient used crutches. His urine, blood urea nitrogen, serum calcium and phosphorus, serum proteins, fasting blood glucose, serum alkaline and acid phosphatase, carbon dioxide combining power of the blood and various serum electrolytes were normal. Roentgenograms of the skull and chest showed normal findings. Roentgenograms of the lower spine and pelvis revealed marked osteoporosis, slightly misshapen femoral heads and greatly thickened femoral necks indicative of possible aseptic necrosis of the heads of the femurs.

Following the hospitalization he received ACTH gel from various physicians prior to reporting to the outpatient clinic of this facility in September 1956. There were no significant changes in his physical status since his last hospitalization although his height is about 2 inches less than that recorded several years ago. He now shows no definite changes indicative of Cushing's syndrome. He uses crutches constantly but appears to be in no great pain. In fact he is usually quite jovial at times rather euphoric, steadily praising the benefits he receives from ACTH and meprobamate (Equanil). He is rather caustic in his expressions regarding physicians who would discontinue the ACTH gel.

Recent roentgenograms of the chest and skull showed no abnormalities. There were pronounced compression changes of the weight

bearing aspect of each femoral head with a lateral concave depression on each side to accommodate the outer lip of the acetabulum. These changes suggested absorption and marked softening of the bone (fig 1). Definite osteoporotic changes were seen in the head of the left humerus and shafts of both femurs, tibias and fibulas (fig 2). There was considerable compression and anterior spreading of the fifth lumbar vertebral body (fig 3).

Figure 1 Roentgenograms of pelvis showing pronounced compression changes of the head of each femur with concave depression laterally on each side to accommodate the outer lip of the acetabulum. (A) Right side (B) Left side

Figure 2 Osteoporosis of long bones due to ACTH gel (A) Left humerus. (B) Shafts of tibia and fibula right

Figure 3 Vertebral fracture from corticotropin therapy. Considerable compression and anterior spreading of the 5th lumbar vertebral body is shown.

Blood chemical and other laboratory tests have remained in normal ranges except for a persistently increased urinary excretion of calcium.

#### SUMMARY AND CONCLUSIONS

Because of the potential dangerous side effects of ACTH and the adrenocorticosteroids the decision to use or not to use any of these agents must be made for each patient. The effects of newer drugs are often deprecated, but it would appear that these hormones are but never forms of symptomatic therapy in many disease states. The physician must weigh any possible benefits of the drugs against the serious bone complications being reported at an alarming rate.

Postmenopausal women should probably not be given the hormones even if roentgenograms of their vertebrae show little evidence of osteoporosis. Serial determinations of urinary calcium excretion and periodic roentgenograms of the spine are indicated if the drugs are to be used over six months. If the hip has been affected, a roentgenographic appearance suggesting aseptic necrosis or Charcot like deterioration of weight-bearing joints may be observed. The most likely cause of this complication

is the greatly increased use to which patients submit joints already damaged by rheumatoid arthritis. Although massive degenerative changes usually occur in weight bearing joints they may be quite generalized.

In most of the reported cases of severe osteoporosis caused by these hormones the well known predisposing factors of advanced age, menopause and restriction of activity were present. The drugs were given for rheumatoid arthritis in most cases. Those showing femoral fractures, osteoporosis was demonstrated in pretreatment roentgenograms, and these occurred in postmenopausal women. However, the case reported vividly documents the severe complications from prolonged hormone therapy in a 43 year old man who was in good physical health prior to maintenance therapy with ACTH gel. The case illustrates the dilemma physicians must face in this ever growing problem, and that the hormones must not be given indiscriminately.

# Acute Puerperal Inversion of the Uterus

JACK E. BYRD *Lieutenant Commander MC USN*  
WILLIAMS BAKER, Jr *Captain MC USN*

**A**CUTE puerperal inversion of the uterus was recognized as a distinct pathologic entity in the earliest medical writings.<sup>1-3</sup> The exact incidence is not known, but has been reported as 1 in 16,420 deliveries.<sup>4</sup>

The symptoms of acute inversion most often tabulated include shock, hemorrhage,<sup>5</sup> pain, and a mass in the vagina. Other signs or symptoms are fundal dimpling or cupping,<sup>6</sup> abdominal pain, retention or incontinence of urine, dysuria, or uremia.<sup>1, 7</sup> When shock occurs, it is more severe than in any other condition in obstetrics and is completely out of proportion to the amount of blood lost.<sup>4</sup>

Almost all possible causes have at some time or other been reported as a reason for puerperal inversion.<sup>8, 9</sup> The most frequently mentioned are mismanagement of the third stage of labor<sup>10, 11</sup> and conditions producing spontaneous inversion of the uterus.<sup>6, 12-16</sup> The advocated methods of management<sup>1, 7, 14-21</sup> are as diverse as are all other phases of this condition, but the majority of authorities favor immediate replacement of the inverted corpus.

## CASE REPORT

An 18 year old woman gravida 1 para 0 was admitted to this hospital on 11 January 1952. The fetal membranes had been ruptured for two hours. There were no contractions or bloody show on admission. The patient had been followed in the prenatal clinic for the last two months of her prenatal course which had been essentially normal. Her last menstrual period was 5 April 1951, and estimated date of confinement was 12 January 1952. Her total weight gain during this pregnancy was 14 pounds and she had no albuminuria or hypertension. Her hemoglobin on 26 January was 10.5 grams per 100 ml and blood type was A Rh positive. A serologic test for syphilis was negative, her urine was normal and roentgenograms of the chest showed no abnormalities.

---

From U S Naval Hospital Camp Lejeune N C. Both authors are now assigned to U S Naval Hospital San Diego Calif.

She was ambulatory on the morning of the third day and was discharged in good condition on the fifth postpartum day. There was no recurrence of bleeding or dimpling of the uterus during her hospital course.

The patient was well on 28 February when she was seen for a six weeks' postpartum examination. She had a slight erosion of the cervix. The fundus was well involuted, symmetrical, anterior and normal in size and configuration. She was seen on 10 April at which time a pelvic examination showed normal findings. She had had a normal menstrual period of four days beginning on 23 March.

The following day a hysterosalpingogram using Priodax (brand of iodoalphonic acid) as a radiopaque media showed a normal configuration of the uterine cavity and tubes with spillage into the peritoneum. There was a questionable loss of the normal uterine fundal concavity, which may indicate an inherent muscular defect in the fundus.

### DISCUSSION

As in all diseases and pathologic conditions, primary emphasis should be on prevention, when causative factors are known.<sup>24-26</sup> There is nothing mysterious about the cause of acute inversion of the puerperal uterus. The basic dynamics are simple. Any hollow elastic organ that is open at one end and is supported to some degree in one plane or another can be invaginated, ultimately to complete inversion, if a force of sufficient magnitude to overcome inertia and elastic resistance is applied at the proper time and in a proper direction. Whether or not the reduced elastic resistance in uterine inversion is atony, thinning at the placental site, or congenital malformation is of little importance, for the end result is the same. In the same respect, the force necessary to overcome this elastic resistance (whether it is increased intra-abdominal pressure, excessive downward pressure on the uterus in expressing the placenta, or excessive traction on the umbilical cord in completing the third stage) is important only insofar as the operator prevents such a force from being applied, or properly applies an opposing force should inversion occur spontaneously.

More women die from accidents during the third stage of labor than during the other two stages combined. At the conclusion of the second stage, if the child has been delivered slowly, the uterus will normally have contracted as the infant is removed. If delivery is too rapid or atony from any cause exists, there will remain a large balloonlike cavity and the predisposing condition for inversion is present, only awaiting the application of the necessary force to set the process in motion.

We believe that inspection of the vagina and cervix is a necessary routine and that exploration of the uterus should be done without hesitation if any undue bleeding or shock occurs. We do

not hesitate in any emergency to use type O, Rh negative blood which has not been cross matched, but has Witebsky's substances added. We do not consider that it is exercising undue caution to routinely start an infusion of 5 per cent dextrose in water in all cases of complicated labor or in which we anticipate trouble.

We firmly believe that immediate replacement of an acutely inverted uterus is essential and that many times this can be done prior to the onset of shock. Simultaneously, assistants should be administering supportive care. The uterus should be replaced gently but firmly, and the procedure should be a simple reversal of the inverting mechanism as described by Barrett. When the replacement has been completed, the hand in the uterus should be extended to the upper limits of the fundus and held there until an oxytocic substance can take effect. Any massage should be upward and at no time should the uterus be squeezed. As the uterine musculature responds to the oxytocic agent the operator should slowly withdraw his hand as it is forced from the uterine cavity. The patient should be closely observed in a continuous postpartum period and Pitocin administered in a constant intravenous drip using 10 units of the substance in 1 000 ml of 5 per cent dextrose in distilled water. The blood bank should have 1 500 ml of compatible whole blood available during the patient's hospital stay. A wide spectrum antibiotic should be given to the patient to prevent sepsis.

Using epinephrine and deep anesthesia to aid relaxation we would not hesitate to attempt reposition of the uterus even when a contraction ring is present. Manual removal of the placenta before or after reposition would depend on individual circumstances. If operative intervention were unavoidable we would first attempt the Spinelli vaginal approach. If this failed the Haultain abdominal method would be performed.

#### SUMMARY

Acute puerperal inversion of the uterus may be either spontaneous or caused by mismanagement of the third stage of labor. Predisposing factors include atony of the uterine muscle thinning at the placental site and congenital malformation. Particularly in the presence of such factors, any force such as increased intra abdominal pressure excessive downward pressure on the uterus in expressing the placenta or excessive traction on the umbilical cord may be sufficient to overcome the inertia and elastic resistance of the uterus and produce inversion.

Immediate gentle manual replacement of the uterus is essential in the treatment of this condition. The operator's hand should be maintained in the uterine cavity until an oxytocic substance can be given and take effect and until the hand is gradually forced from the cavity.

The case reported in this article demonstrates that prompt, adequate treatment may prevent serious complications in this emergency

### A MESSAGE FROM THE A M A

Last month's article outlined the comprehensive American Medical Association study project on medical professional liability. In particular it dealt with malpractice claims involving medical officers or federally employed physicians.

This month's Message concerns state legislative proposals as they pertain to medical professional liability. State laws are applicable in malpractice suits against civilian physicians while as pointed out in the preceding Message the Federal Tort Claims Act is applicable to claims involving military physicians. Although there have been isolated efforts to enact state legislation relating specifically to actions against physicians, relatively few laws have been enacted that would place physicians in a more vulnerable position than other tort defendants.

An unsuccessful proposal in Montana in 1971 for example would have made malpractice a felony. It is fortunate that the Montana proposal failed of enactment even though it did go on to provide that nothing therein should be construed to prohibit a physician or surgeon from administering medicine or otherwise treating patients in cases where the effect of the medicine or treatment might be dangerous to life or injurious but where the administration thereof is in accordance with sound approved medical practice. Undoubtedly many new practitioners would have been scared away from Montana if that legislation had been enacted. It would probably have caused physicians in Montana to hesitate a long time before using some of the newer drugs, treatments or techniques.

A Kansas law although relating only to patients in state hospitals who receive psychiatric shock treatments went to the opposite extreme by denying a cause of action against the physician unless he has been guilty of gross negligence.

Georgia law provides that a physician must bring to the exercise of his profession a reasonable degree of care and skill. It appears that this type of approach is best in the long run for both patient and physician. It doesn't require the physician to

# A MESSAGE FROM THE A M A

910

bo n miracle man, nor does it require the patient to establish a practically impossible degree of proof

There have been suggestions as to the need of "modernizing and reforming" the general law applicable to personal injury cases. For example, some states, through court decisions, have applied the doctrine of Comparative Negligence or the doctrine of Last Clear Chance. Usually, at common law, if the plaintiff of his own negligence contributes in any way to the injuries which he receives, he is denied a recovery from the defendant. This is the doctrine of Contributory Negligence and, if applicable and established, is a valid and complete defense in a negligence action. Many have contended that where the degree of contributory negligence is minute as compared with that of the defendant, a complete denial of recovery is neither fair nor reasonable. It has been further argued that where a defendant has the last opportunity to avoid an accident, even though there was some negligence on the plaintiff's part in placing himself in a hazardous position, the defendant should be held responsible for the resulting injuries. These arguments make considerable sense and have, in fact, resulted in the enactment of state laws establishing that point of view. One of the most recent of such laws was enacted in Massachusetts in 1954.

As to the question of burden of proof, it has been well established that as a general rule medical expert testimony is necessary to explain to a jury the standard of care required in a particular case, because logically a lay jury is held to be incapable of determining such a standard by itself. An unsuccessful proposal in Vermont would have changed that rule by providing that it would not be necessary in malpractice actions for the plaintiff to introduce expert testimony to establish a standard of care and skill for the purpose of showing the failure of defendant to observe such care. Another general rule of law provides that text books may not be admitted in evidence to establish the truth of statements found therein because of the fact that the author is not present and subject to cross examination. However, both Massachusetts and Nevada have enacted laws permitting the introduction of such evidence. The Massachusetts statute requires that, not less than three days before the trial, notice must be given the adverse party of such intention stating the name of the writer of the statement and the title of the treatise, periodical, book, or pamphlet in which it is contained.

Under the doctrine of *res ipsa loquitur* (the thing speaks for itself) it is not necessary to introduce expert testimony in those cases of accident or injury which clearly could not have happened unless someone was negligent. The mere showing of the

circumstances of the accident is sufficient to establish a prima facie case. Under such a presumption of fact the jury may infer that the accident or injury resulted as a consequence of negligence. An example would be where, following an operation a sponge was left in the patient's abdomen.

In some cases of malpractice where the plaintiff was unable to obtain medical witnesses the courts have gone too far in converting the doctrine of *res ipsa loquitur* into a rule of symmetry. It is entirely possible that should the courts believe there still remain valid and legitimate cases in which plaintiffs are unable to persuade reputable practitioners to testify in their behalf the state legislatures will be requested to solve the problem. Mayoe this attitude should serve as a warning to those members of the medical profession who are unobtainable as expert medical witnesses for the plaintiff.

## DEATHS

**BROWN** Dale Eugene First Lieutenant MSC USAR of Culver Ind stationed at 63d Medical Detachment Germany graduated in 1950 from Indiana University Bloomington Ind commissioned a Second Lieutenant in the United States Army Reserve 21 September 1951 died 4 April 1957 age 30 in Germany as result of a vehicle accident

## SECRETARY GENERAL OF WORLD MEDICAL ASSOCIATION VISITS RANDOLPH AIR FORCE BASE

Doctor Louis H. Bauer, Secretary General of the World Medical Association and past President of the American Medical Association, recently visited the School of Aviation Medicine, Randolph Air Force Base, Tex., and addressed the student officers. The photograph shows Doctor Bauer with Major General Otis O. Benson, Jr., Commandant of the School. Dr. Bauer himself was Commandant of the School after World War I and is at present a member of the Board of Visitors. Air University of which the School of Aviation Medicine is a part. He is a founder of the Aero Medical Association and Editor Emeritus of its journal *The Journal of Aviation Medicine*.

General Benson recently advanced to the two-star rank. He has had a distinguished career in aviation medicine. Presently assigned as Commandant of the School of Aviation Medicine for the second time in his career, he has like Dr. Bauer been the recipient of the John Jeffries Award of the Institute of Aeronautical Sciences and the Theodore C. Lyser Award of the Aero Medical Association. He was awarded an honorary Doctor of Science degree from the University of Montana in 1955. General Benson is Vice Chairman for Aviation Medicine of the American Board of Preventive Medicine.

## ASSISTANT SECRETARY OF DEFENSE VISITS MILITARY AVIATION MEDICAL FACILITIES

During the first week in April the Honorable Frank B. Berry, Assistant Secretary of Defense (Health and Medical), was accompanied by guests from the Department of National Defence of Canada and by members of his own Civilian Health and Medical Advisory Council on an orientation visit to several military aviation centers in Alabama and Florida.

Arrival at Forrest Sherman Field of Honorable Frank B. Berry, Assistant Secretary of Defense (Health and Medical), with members of the Department of Defense Civilian Health and Medical Council and medical personnel of the Canadian Department of National Defence.

Distinguished Canadian guests included Dr. J. A. MacFarlane, Chairman, Canadian Forces Medical Council; Brigadier A. A. Hunter, Commander, Air Services Department of National Defence; Air Commodore A. A. G. Corbet, Director General of Medical Services; Royal Canadian Air Force; Dr. R. Ian Macdonald, Consultant in Medicine to the Canadian Forces Medical Council; and Wing Commander J. C. Wickett, Royal Canadian Air Force Medical Liaison Officer, Canadian Joint Staff, Washington.

Others accompanying Dr. Berry were Dr. E. H. Cushing, Deputy Assistant Secretary of Defense (Health and Medical); Dr. Melvin A. Casberg, Vice President, Medical Affairs, University of Texas; Dr. Thomas P. Fox, Professor of Oral Surgery, Jefferson Medical School; Dr. Anthony J. J. Rouke, Hospital Consultant, New Rochelle, N. Y.

June 1957)

## DIGNITARIES VISIT MEDICAL FACILITIES

923

Dr James E McCormack Assistant Vice President, Presbyterian Hospital, New York City Dr Wilbert C Davison, Dean, Medical School Duke University, Surgeon Commander Frank P Ellis, Her Majesty's Royal Navy and Mrs Mildred L McBlair, Executive Assistant to Dr Berry

At the Headquarters Air University, Maxwell Air Force Base the group was briefed on the missions of the Air War College, the Air Command and Staff College the Air Force Institute of Technology and the Air Force Reserve Officers Training Corps The group also visited the 3810th U S Air Force Hospital

Dr Berry being greeted at Eglin Air Force Base by Major General Robert W Burns Commander of the Air Proving Ground Command, Colonel Charles H Morhouse Commander of the 3201st U S Air Force Hospital and Colonel Frank H Mears Commander of Eglin Air Force Base

At nearby Gunter Air Force Base, there was a comprehensive briefing on the Gunter Branch of the School of Aviation Medicine U S Air Force Air University followed by a tour of many of the classrooms and laboratories

At the Headquarters, Naval Air Training Command Naval Air Station Pensacola the group was briefed both on Naval Air Basic Training and on the training and research activities of the School of Aviation Medicine Tours were made of all the School facilities The group also visited the U S Naval Hospital Pensacola where Dr Berry met with the hospital staff

The fourth visit of Dr Berry's party was to Eglin Air Force Base where they inspected the facilities of the 3201st U S Air Force Hospital with an explanation of the mission of the Air Proving Ground

## MILITARY SURGEONS CONVENTION CHAIRMEN ANNOUNCED

*Committee chairmen for the 64th annual convention of the Association of Military Surgeons of the United States which will be held at the Hotel Statler in Washington D C 28-30 October 1957 have been announced by the association President Colonel Amos R Kohnitz MC Maryland National Guard They are General Chairman Major General Paul I Robinson MC USA Director Office for Dependents Medical Care Program Chairman Colonel Robert C Kimberly MC Maryland National Guard Scientific Exhibits Captain William M Silliphant MC USN Director Armed Forces Institute of Pathology and Commercial Exhibits Mr Steven B Herlitz New York City*

*The new General Chairman Major General Paul I Robinson MC USA*

Membership in the Association is open to all present and former officers of the Medical, Dental, Veterinary, Medical Service Nurse, and Medical Specialist Corps of the Army, Navy, and Air Force, as well as personnel from the Public Health Service and Veterans Administration.

Each year the convention draws some 2,000 members from all parts of the Nation, as well as leading medical members of military organizations from other countries. The theme of the 64th annual convention will be "Professional Excellence—the Criterion of Military Medicine."

---

#### INTERNATIONAL NAVAL REVIEW

An International Naval Review, the first staged in this country since 1907, will be held on 12 or 13 June in Hampton Roads, Va., in connection with the celebration of the anniversary of the first permanent settlement by English speaking colonists in the United States at Jamestown, Va.

This full dress review is expected to be the largest ever held anywhere, with 27 nations invited to send ships to Hampton Roads for the occasion. The nations participating will be those who have some reason to take part in celebrating the founding of Jamestown and the colonization of North America.

Reviews of Recent Books

and 50 plates W B Saunders Co Philadelphia Pa 1957 Price  
\$12 50

This is an old friend and standby that fulfills its purpose of giving  
its users "an up-to-date medical dictionary sufficiently full for the  
varied requirements of all classes of medical men." Appropriately  
The American Illustrated Medical Dictionary has been renamed Dor  
land's Illustrated Medical Dictionary in attune with the title by which  
it has been commonly known

The page size of the Dictionary has been increased slightly to make  
possible the inclusion of thousands of new terms. Many definitions  
have been rewritten to keep pace with "changing concepts or expanded  
knowledge" and numerous typographic errors that appeared in the  
twenty second edition have been corrected. The rewritten tables of  
the arteries, muscles, and nerves are based on material prepared under  
the sponsorship of the National Academy of Sciences and conform in  
part to the Nomina Anatomica as revised by the International Anatomical  
Nomenclature Committee. A welcome and useful new feature is Notes  
on the Use of This Dictionary

The typography is good. Phonetic respelling of main entries is as  
simple as possible and immediately follows the boldfaced entry

All in all this dictionary continues to live up to its wide reputation  
as a significant and essential desk reference for students, medical  
authors or editors, physicians, and others interested in medicine and  
allied fields —E. W. MARTIN

THE UNITED STATES AIR FORCE DICTIONARY edited by Woodford Agee  
Heflin, 578 pages D Van Nostrand Co Inc Princeton N J 1957  
Price \$4 75

Since the flight of the Wright brothers at Kitty Hawk in 1903 there  
has been a build up of terminology that is peculiar to aeronautical  
sciences and allied disciplines. This terminology received its first  
momentum in World War I while there was provided a tremendous  
impetus to this trend during World War II

At first one might think that the language of airmen was jargon or slang which had little genuine application and could be hardly understood or deciphered. This work dispels that concept.

Of particular interest among the 16,000 entries are the authorized and unauthorized abbreviations and designations of the Air Force which have often confounded the average military reader. There are also listed meteorologic, navigational, electronics, and radar terms which are in common usage today but perhaps not always fully understood. In addition many scientific and medical terms some applicable to aviation medicine, are clearly defined.

It is of particular value and interest to those who are engaged in writing for official and nonofficial military publications. Perhaps this may be termed a dictionary of special vocabulary for certainly the vast majority of the terms cannot be found in Webster's. The book reflects fine workmanship of a large staff of interested editors both civilian and military at the Air University.

—PAUL V DAVIS Col USAF (MC)

**NOTES ON ATOMIC ENERGY FOR MEDICAL OFFICERS** by The Royal Naval Medical School Alverstoke Hampshire, England 169 pages illustrated Philosophical Library, Inc, New York N Y 1956. Price \$4.75

This small handbook prepared by the Staff of the Royal Naval Medical School provides basic information on the phenomenology of atomic explosions and of the consequences to man. Gamma radiation effects are dealt with mainly.

There are also brief chapters on atomic structure, nuclear physics and monitoring instruments which serve as useful introductions to these subjects. The appendix includes the periodic table of elements a short table of physical constants and certain peacetime tolerances for radiation exposures.

The book will be of value to the medical officer desiring a simplified yet concise account of atomic energy as it relates to military medicine.

—KENT T. WOODWARD Maj MC USA

**PHYSICAL EXAMINATION IN HEALTH AND DISEASE** by Rudolph H Kampmeier A B M D 774 pages illustrated 2d edition F A Davis Co Philadelphia Pa 1957 Price \$9.50

An organized and practical approach to physical examination—the original means of diagnosis—is used in this text.

As in the first edition two chapters are devoted to each body region the first dealing with normal findings the second with abnormal and disease states. Anatomic, pathologic, and physiological correlations are stressed. Each chapter is liberally supplemented with photographs.

The entire opening chapter is devoted to history taking. There are no separate chapters on neurologic examinations. This part of the examination being included in the various chapters on separate regions of the body.

This book is well written and should prove of value both as a text for students and as a reference book in medical libraries.

—JULES J McNEENEY Lt Col MC USA

**GUIDE TO MEDICAL WRITING** A Practical Manual for Physicians, Dentists, Nurses, Pharmacists by Henry A Davidson M D 338 pages 11 illustrated The Ronald Press Co New York N Y 1957 Price \$5

Although many physicians at one time or another write professional articles few are familiar with the requirements of good medical writing. The practitioner's energies are so largely consumed by his major work that he has little time or taste for the cultivation of skill in writing.

This guide is intended to help him develop such skills. It attempts to show the prospective author how to pin down his ideas, how to organize his subject matter, how to master the mechanics of presentation, and how to put it in readable form. Emphasis is placed on practical points—research methods, outlining, revision, summaries, choice of vigorous words, and the arrangement of pictures and charts. In addition to advice on writing skills, the book covers the intricacies of punctuation, spelling, grammar, and bibliography. Particularly valuable for constant reference are the dosage conversion tables and lists of generic equivalents to the trade names of drugs.

One might suggest that a more complete breakdown of the text into headings of co-ordinate grade or superior and subordinate grades and a more complete index would increase the effectiveness of the book as a ready reference. As an adjunct to other texts on the subject, however, this work certainly deserves shelf space in the library of anyone who attempts medical writing, particularly the novice.

—FRANKLIN M. ROBERTS Lt MC USNR

**THE CIBA COLLECTION OF MEDICAL ILLUSTRATIONS** Volume 3 A Compilation of Paintings on the Normal and Pathologic Anatomy of the DIGESTIVE SYSTEM Part III Liver, Biliary Tract and Pancreas Prepared by Frank H Netter M D Edited by Ernst Oppenheimer M D Five sections XV to XIX 165 pages 133 colored plates Publications Department CIBA Pharmaceutical Products Inc Summit N J 1957 Price \$10 50

Most practicing physicians are familiar with the colored plates on many systems and disease states distributed from time to time by CIBA. This volume is much more than merely a collection of those previously distributed booklets. It is a compilation of most aspects of the liver, pancreas and biliary tree including anatomy, physiology, biochemistry, diagnostic methods and disease states simplified to two dimensional multicolored plates which are easily understandable.

June 1957)

## REVIEWS OF RECENT BOOKS

0220

These interpretive visual demonstrations depict the newer concepts of liver structure functional aspects as related to morphology, pathogenesis of hepatic and pancreatic disease, and refined discriminations of various entities

For purposes of continuity the first section covers normal anatomy and the second physiology and pathophysiology including diagnostic tests. A full section is then devoted to each of the organs namely, diseases of the liver, diseases of the gallbladder and bile ducts, and diseases of the pancreas.

Each group of plates is accompanied by a well written discussion of the topic. An excellent bibliography for reference for more complicated discussion of the subjects is presented in the back of this book.

This volume is not a substitute for any one of the excellent text books on these organs but is a supplement, leading to a clearer understanding of this complicated area of the human body. It should prove invaluable to the resident in internal medicine or surgery.

—LESTER P. POPE Capt MC USN

THE YEAR BOOK OF DRUG THERAPY (1956 1957 Year Book Series) edited by Harry Beckman M D 514 pages illustrated The Year Book Publishers Inc Chicago Ill 1957 Price \$6 75

A yearbook on drug therapy is most appropriate and necessary now a days when there are many new chemicals and numerous trade names for similar products. A number of abstracts in this volume discuss unexpected and undesired reactions to therapy. This information is especially important because while the new drugs have many advantages, their potentialities for harm are often equally great.

In this particular edition the choice of the articles is very good and there is a liberal sprinkling of editorial footnotes which adds to the interest and value of the book. This book is a valuable addition to any doctor's library allowing rapid survey of articles on therapy from a great many more sources than most of us have time to examine.

—JAMES L. TOBIN Col. USAF (MC)

PROCEEDINGS OF THE THIRD NATIONAL CANCER CONFERENCE Detroit Mich June 4 6 1956 Sponsored by American Cancer Society Inc and National Cancer Institute U S Public Health Service 961 pages illustrated J B Lippincott Co Philadelphia Pa 1957 Price \$9

This is a comprehensive and up to-date review of the broad field of cancer and upholds the high standards achieved on the preceding conferences of 1949 and 1952. The cancer problem is covered from the broad aspects of epidemiology as a tool in research to detailed considerations of various neoplasms involving specific organs. It represents the combined efforts of over two hundred essayists and discussers who are recognized authorities in the fields of cancer research, diagnosis prognosis and treatment.

The first 13 pages are devoted to the opening remarks which clearly set forth the ideals and purpose of the conference and the summaries which are masterpiece condensations of the vast material contained in this volume. The second part consists of general lectures concerning the subjects of epidemiology, radiation neoplasia, virus etiology, chemical effects of growing tumors on the host with special reference to iron factors influencing curability, and measurement of morbidity. The third part consists of symposiums and panels covering cancer of the breast, prostate, lung, head and neck, female genital tract, gastrointestinal tract, lymphomas and leukemias, and chemotherapy. The end results of treatment are covered in detail.

The American Cancer Society and the National Cancer Institute co-sponsors of this book deserve the highest commendation for this invaluable compilation of information on cancer.

—FRANK M. TOWNSEND Col USAF (VC)

**CLINICAL UROLOGY FOR GENERAL PRACTICE** by Justin J. Cordonnier  
M. D. F. A. C. S. 237 pages illustrated Th. C. & Mosby Co. St.  
Louis Mo. 1956. Price \$6.75

In 233 pages of text the author has condensed all the urologic information which the intern or general practitioner will need and for the specialist urology is outlined in such a succinct, factual manner as to make it a refreshing reference manual.

Diagnosis and treatment of the surgical diseases of the genitourinary tract are described briefly and in an up-to-date manner except for surgical techniques. Pathology is illustrated by photomicrographs and roentgenograms of a size and detail rarely encountered today and rivaled only in clarity by the refreshingly large textual print. The chapters are predicated on pathology, simply indexed and followed by ample current references which reflect the didactic approach of this noted professor.

Any urologist perusing Dr. Cordonnier's book might even say, "I wish I had written that!"

—CHARLES W. HOFFMAN J. U. Col. MC USA

**PRACTICAL DERMATOLOGY** by Samuel H. Peck, B. S., M. D. with Lawrence L. Palusz, M. D., Ph. D. 360 pages illustrated. Landsberger Medical Books, Inc. Distributed by The Blakiston Division, The McGraw-Hill Book Co., Inc. New York, N. Y. 1956. Price \$7.

According to the preface, this book was written for the busy general practitioner. The first chapter is devoted to general remarks on diagnosis and treatment and is exceptionally well written. A discussion of industrial dermatoses is excellent and brief. The rest of the book is devoted to clinical dermatology. There are 122 black and white photographs. Several of these, although technically good, are not particularly illustrative of the designated disease.

Throughout the book the authors stress the use of simple forms of treatment, such as the statement on page 24 that wet dressings or a soothing ointment will frequently do as well or better than expensive steroids. In general, they appear overoptimistic as to the results of treatment but do not overemphasize the use of x ray and steroids.

The authors are to be commended for the brevity of their descriptions. However, in some diseases the discussions are so short that they lack clinical descriptions. The book is well written, however, and can be recommended to the general practitioner.

—MARLYN MARSS, CAPT. MC USA

**ALLERGIC DERMATOSES DUE TO PHYSICAL AGENTS** edited by Rudolf L. Baer M D 110 pages illustrated Published by New York University Press Distributed by J B Lippincott Co, Philadelphia, Pa 1956. Price \$3

In this symposium on allergic dermatoses the authors have in a few pages, summarized what is presently known on the subject of physical dermatologic allergy. Included in the six chapters of this book is a discussion of the general treatment of allergic hypersensitivity to physical agents including trauma, light, heat, and cold.

This little volume is primarily of interest to dermatologists and allergists and has its place in their libraries as it is the only symposium entailing and correlating the various physical cutaneous sensitivities. Though the discussion of the various conditions is brief, the bibliography given at the end of each chapter is most adequate. This compendium is also of value to students of dermatology and allergy in preparing for their specialty boards.

—LOUIS S. LFLAND, COL. MC USA

**MODERN OFFICE GYNECOLOGY** by George Blumick M D F A C S, and Sherwin A Kaufman M D F A C S 218 pages 47 illustrations Lea & Febiger Philadelphia Pa 1957 Price \$1.50

A slightly different approach is used in this textbook. The first of three sections deals with the most common gynecologic complaints presented such as abnormal vaginal bleeding, amenorrhea, dysmenorrhea, infertility, leukorrhea, and menopause. Under each heading a differential diagnosis is presented and one or two accepted forms of therapy are given.

The second section contains illustrations on the techniques of performing bimanual pelvic examinations, biopsies, cauterizations, pessary insertions, contraceptive fittings, and taking smears. The diagrammatic drawings are in black and white. The cytology and gross pathology sections contribute very little of value. The third section is really an amplification of the first in that it consists of a bibliography that covers the controversial issues of diagnosis and treatment that were outlined in part one. This bibliography is supplemented with clinical abstracts. Inpatient gynecologic treatment is not discussed.

Although this textbook would be of definite aid to the general practitioner and perhaps to the senior medical student and intern it would be of limited value to the resident or gynecologist

—J WILSON HUSTON Capt MC USN

**CLINICAL UNIPOLAR ELECTROCARDIOGRAPHY** by Bernard S Lipman  
A B M D F A C P and Edward Massie A B M D F A C P  
3d edition 397 pages illustrated The Year Book Publishers Inc  
Chicago Ill 1956 Price \$7 50

This book presents the complicated subject of electrocardiography in a simple and practicable manner as free from detailed and complex discussions as possible. It is intended primarily for those not too experienced in electrocardiography. This edition maintains much the same format of the previous ones with a short introduction including a history and description of the subject. The clinical aspects of electrocardiography such as position of the heart, ventricular enlargement, bundle branch block and myocardial infarction, abnormal patterns and congenital heart disease are discussed. Following the clinical discussion there is a short chapter on the interpretation of the electrocardiogram and a new chapter on spatial vector interpretation followed by a discussion of the cardiac arrhythmias.

The remainder of the book contains a well selected and reproduced illustrative group of 12 lead electrocardiograms including the standard limb leads. The textual material is certainly not controversial. It is not written for the beginner in electrocardiography and because it includes the generally accepted theory and interpretations it is not for the experienced electrocardiographer. There is a good bibliography arranged in alphabetical order of the authors' last names covering the present concepts in electrocardiography.

—WILLIAM D PRESTON Col USAF (MC)

**CHILDREN'S EYE PROBLEMS** by Emanuel Krinsky M D 175 pages  
illustrated Grune & Stratton Inc New York N Y 1956 Price \$6

Although this book is intended primarily for the pediatrician and the general practitioner, the ophthalmologist will find it helpful in dealing with the child as a whole by emphasizing environmental, psychologic, hereditary and systemic influences. The child psychiatrist and school nurse will find this book of value because emphasis has been placed on extraneous factors often responsible for a child's true or imaginary eye problem.

It offers a simple, practical screening method for the general practitioner or public health worker to detect possible eye disorders. False notions and misconceptions by the lay are discussed.

The author stresses that greater reliance is to be placed on objective examination in children. He gives methods of examination using simple instruments which have proved useful in his hands. The book is recommended for all those who see children in their daily practice. —KENNETH E HUDSON Lt Col MC USA

**MUSCLE RELAXANTS IN ANESTHESIOLOGY** by Francis F. Foldes M.D.  
 American Lecture Series, Publication No. 294 A Monograph in The  
 Baerson Division of American Lectures in Anesthesiology, edited  
 by John Adriani M.D. 210 pages illustrated Charles C. Thomas,  
 Publisher, Springfield Ill. 1957 Price \$5.50

Dr. Foldes is well known as an investigator in the field of anesthesiology and is well qualified to write a review on muscle relaxants as they are used in the practice of anesthesia.

The first 56 pages of this book deal with the chemistry, physiology and pharmacology of muscle relaxants. The theories of the mode of action of polarizing and depolarizing relaxants is presented with very clear diagrammatic illustrations. The scientific discussion of the drugs although technical, is clear and easy to follow.

The last hundred pages deal with the clinical application of the muscle relaxants. Dr. Foldes describes very specifically how he uses each drug, the indication and contraindication of each relaxant and the complications that result from the use of muscle relaxants and the management of these complications. During his discussion of anesthesia for the aged, the asthmatic and the cardiac patient, he brings out many fundamental principles of anesthesia.

I especially like the way each chapter starts with an outline thus directing the reader to the highlights of the chapter. There is an impressive bibliography of 414 references and the index is adequate.

—DANIEL M. PINDO Comb. MC USA

**POSITIONING IN RADIOGRAPHY** by A. C. Clark M.B.E.F.S.R. 655  
 pages 2150 illustrations 7th edition Grune & Stratton Inc., New  
 York N.Y. 1956 Price \$29

Through successive editions this text has been enlarged and modernized and has successfully followed the trend and new ideas in radiographic technique. The standard positions used in routine radiography as well as the unusual positions required in special examination are clearly described and illustrated. Line drawings and labeled photographs graphically correlate the external topography with the radiograph desired in a clear manner. Standard exposure factors are included for each examination.

Special sections on pelvimetry, placentography, dental radiography, myelography, stereography and angiography are included. Notes on the use of contrast media and a section on radiation exposure are also of timely interest. The discussion of theory in each section makes the volume additionally useful to those engaged in teaching. The text is well indexed and the desired subject is readily found. The use of accessory equipment such as cones, grids and special holding devices is well described.

The new edition continues to justify its earned position as one of the foremost texts on radiographic technique.

—SYLVESTER F. WILLIAMS Capt. MC

# Monthly Message

As the Fourth of July approaches, I should like to print a letter\* written by a doctor in the Army from Camp Wilmington, North Carolina on July 13 1776, that it may remind all of you who are now privileged to serve with the Armed Forces, of earlier days and more difficult conditions. At that time we were fighting for the same independence which other nations desire today. Independence is not to be confused with "unbridled license," but is rather the freedom of living among men and nations with respect by all for one another.

Camp at Wilmington July 13 1776

"Sir

I beg the honor of you to let me know whether there is any provision made by Continental Congress For supporting the regiments in this Province with medicines I have hitherto used my own but unless I have a new supply shall soon be out of some of the most principle articles I could have supplied myself had I been supplied with mooney but the Paymaster refuses to advance any mooney For that purpose The consumption of medicines is very great For 3 weeks Past I've had From 20 to 30 in the hospital belonging to the 5th regiment The sickly season is now coming on Fast and unless I'm speedily supplied I shall be destitute of such medicines as I find of most service here I furthermore beg the favor of you Sir to let me know what a surgeon's pay is how many rations he is allowed whether there is any more allowed if so what his pay is to be and who appoints Him Your compliance will much oblige

"Sir your most Obedient Hum Servant

## PHYSIOLOGICAL INVESTIGATIONS IN THE FLYING SAFETY PROGRAM OF THE FLYING TRAINING AIR FORCE

WILLIAM H. LAWTON *Colonel USAF (MC)*

**T**HE subject for today is one in which we are all vitally interested, namely, flying safety.

I came to the Flying Training Air Force (FTAF) when it was first organized in 1951, and since then everyone in my office has been working closely with our Flying Safety people, with our Training and Operations Section, with our Base Commanders, and also with our Commanding General in an effort to reduce the aircraft accident rate. This accident rate has fallen from a high of 56.2 per 100,000 flying hours in 1951 to a low of 10.4 in 1956. In the Surgeon's Office, we have been working along the lines of physiological investigation to improve flying safety. The methods we have used in helping reduce our accident rates will be presented.

The importance of hypoxia<sup>1</sup> as related to the safety of flying personnel is well recognized, and elaborate measures have been taken to prevent it. Two other conditions which are physiologically abnormal, the symptoms of which may be confusing or add to the symptoms of the hypoxic syndrome, are hyperventilation with hypocapnia and hypoglycemia, or relative hypoglycemia.

### HYPERVENTILATION

Hyperventilation in an aviator, according to Lillehei and Balke,<sup>2</sup> if progressive, may reduce the carbon dioxide below a critical

<sup>2</sup>From Flying Training Air Force, Waco, Tex.

level which results in performance impairment, tetany, and unconsciousness. These authors found that lowering the alveolar carbon dioxide tension below 25 mm of mercury by voluntary hyperventilation in normal young men caused a significant impairment of psychomotor performance as tested on the Air Force Complex Coordinating Apparatus. In addition, tetany with severe spasms of the wrists and fingers resulted when an average of 3.5 liters of carbon dioxide per square meter of body surface area were lost from the body reservoir.

Balko, Wolls, and Clark,<sup>3</sup> continuing the work on hyperventilation at the U S Air Force School of Aviation Medicine, confirmed the findings of the earlier study and added that susceptibility to hyperventilation varied greatly from individual to individual, some demonstrating severe tetany, others only slight tingling or no symptoms at all when exposed to the same experimental conditions. Of the 26 student pilots subjected to in flight tests it was observed that otherwise very efficient students made mistakes, became progressively confused, and showed low carbon dioxide values. Symptoms noted during mechanically induced hyperventilation in the laboratory are summarized in table 1. Despite these subjective and objective symptoms, it was apparent that "healthy young individuals in good physical condition have a good resistance to relatively severe degrees of hypocapnia. For that reason there will continue to be much speculation about the possibility of aircraft incidents or accidents caused by hyperventilation."

# FLYING SAFETY PROGRAM

939

During pressure breathing it was also noted that the earlier symptoms of hypoxia and hyperventilation with hypocapnia are similar and confusing

The work cited above, coupled with the earlier work of Pinshaw and co-workers, and Rushmer and Bond,' suggested strongly that some of our accidents were due to hyperventilation rather than to hypoxia. In order to get more specific information on the differential diagnosis, a Physiological Near Accident Report was instituted in our Command during the latter part of 1952

During the spring of 1953, an incident occurred in one of our low pressure chambers at a simulated altitude of only 8,000 feet. Inasmuch as hypoxia does not occur ordinarily at altitudes below 12,000 feet, the Flight Surgeon and the Aviation Physiologist in charge of this case were interviewed directly, and it was determined that the subject involved was observed to have had definite hyperventilation preceding his collapse

A second incident, occurring some three months later, was also observed in a low pressure chamber. The student undergoing indoctrination in aviation physiology was subjected to mild hypoxia by disconnecting his oxygen hose at 30,000 feet. This particular student insisted on leaving his hose disconnected longer than directed, and he very shortly collapsed, apparently from hypoxia. His oxygen supply was re established and his recovery was prompt, however, he began breathing very rapidly and deeply, and at 27,000 feet he lost consciousness again, apparently this time from apnea or a combination of apnea and hypoxia. Each time during recovery hyperventilation was repeated, and the subject relapsed at 17,000 feet and again at 8,000 feet. This incident seems to confirm the possibility of hypoxia acting as a "triggering mechanism" for hyperventilation

Following the two incidents outlined above, 64 Physiological Near Accident Reports were reviewed and the impression was gained that many of these could be charged to hyperventilation. In November 1953, we started an intensive indoctrination program regarding hyperventilation, emphasizing the symptoms, dangers, and preventive measures. It was thought that the young student aviator was predisposed to hyperventilation when, with his helmet and face mask in place, he was tightly strapped into the seat of a jet aircraft and the canopy closed with a "thump". He was further conditioned by formation flying at altitudes of 20,000 feet or higher so that any further increase in the stress factors might cause involuntary hyperventilation, with performance impairment and with resulting near accident or actual disaster. One student flying solo a P-6 aircraft reported to the tower that he was in trouble but landed safely through the efforts of an instructor flying wing, plus radio instructions from the Flight Surgeon. On landing, he explained that he could not grasp the

level which results in performance impairment, tetany, and unconsciousness. These authors found that lowering the alveolar carbon dioxide tension below 25 mm of mercury by voluntary hyperventilation in normal young men caused a significant impairment of psychomotor performance as tested on the Air Force Complex Coordinating Apparatus. In addition, tetany with severe spasms of the wrists and fingers resulted when an average of 3.5 liters of carbon dioxide per square meter of body surface area were lost from the body reservoir.

Balke, Wells, and Clark,<sup>3</sup> continuing the work on hyperventilation at the U S Air Force School of Aviation Medicine, confirmed the findings of the earlier study and added that susceptibility to hyperventilation varied greatly from individual to individual, some demonstrating severe tetany, others only slight tingling or no symptoms at all when exposed to the same experimental conditions. Of the 26 student pilots subjected to in flight tests, it was observed that otherwise very efficient students made mistakes, became progressively confused, and showed low carbon dioxide values. Symptoms noted during mechanically induced hyperventilation in the laboratory are summarized in table 1. Despite these subjective and objective symptoms it was apparent that "healthy young individuals in good physical condition have a good resistance to relatively severe degrees of hypocapnia. # FLYING SAFETY PROGRAM

939

During pressure breathing it was also noted that the earlier symptoms of hypoxia and hyperventilation with hypocapnia are similar and confusing

The work cited above, coupled with the earlier work of Pinshaw and co-workers<sup>1,2</sup> and Rushmer and Bond,<sup>3</sup> suggested strongly that some of our accidents were due to hyperventilation rather than to hypoxia. In order to get more specific information on the differential diagnosis, a Physiological Near Accident Report was instituted in our Command during the latter part of 1952

During the spring of 1953, an incident occurred in one of our low pressure chambers at a simulated altitude of only 8,000 feet. Inasmuch as hypoxia does not occur ordinarily at altitudes below 12,000 feet, the Flight Surgeon and the Aviation Physiologist in charge of this case were interviewed directly, and it was determined that the subject involved was observed to have had definite hyperventilation preceding his collapse

A second incident, occurring some three months later, was also observed in a low pressure chamber. The student undergoing indoctrination in aviation physiology was subjected to mild hypoxia by disconnecting his oxygen hose at 30,000 feet. This particular student insisted on leaving his hose disconnected longer than directed, and he very shortly collapsed, apparently from hypoxia. His oxygen supply was re-established and his recovery was prompt, however, he began breathing very rapidly and deeply, and at 27,000 feet he lost consciousness again, apparently this time from apnea or a combination of apnea and hypoxia. Each time during recovery, hyperventilation was repeated, and the subject relapsed at 17,000 feet and again at 8,000 feet. This incident seems to confirm the possibility of hypoxia acting as a "triggering mechanism" for hyperventilation

Following the two incidents outlined above, 61 Physiological Near Accident Reports were reviewed and the impression was gained that many of these could be charged to hyperventilation. In November 1953, we started an intensive indoctrination program regarding hyperventilation, emphasizing the symptoms, dangers, and preventive measures. It was thought that the young student aviator was predisposed to hyperventilation when, with his helmet and face mask in place, he was tightly strapped into the seat of a jet aircraft and the canopy closed with a "thump". He was further conditioned by formation flying at altitudes of 20,000 feet or higher so that any further increase in the stress factors might cause involuntary hyperventilation, with performance impairment and with resulting near accident or actual disaster. One student flying solo a T-6 aircraft reported to the tower that he was in trouble but landed safely through the efforts of an instructor flying wing, plus radio instructions from the Flight Surgeon. On landing, he explained that he could not grasp the

stick because his hands were like claws. Another student flying a PA 18 aircraft with an instructor found his hands frozen to the struts. After being landed by the instructor, it required 10 minutes and the efforts of two persons to free the student's hands.

In our indoctrination program young pilots are instructed if flying under 10 000 feet when they begin to hyperventilate to simply hold the breath as long as possible and then resume breathing near the normal rate of 14 per minute. When flying at altitudes where hypoxia can be a factor and it is necessary to differentiate between hypoxia and hyperventilation the pilot is told to first turn his oxygen regulator to 100 per cent oxygen and take three breaths. If he is not improved or possibly feeling a little worse he should then try holding his breath as long as possible, and then resume at the normal rate of 14 per minute. It might be argued here, that taking three more breaths when already hyperventilating might be courting disaster. This has not occurred in our experience.

During the year 1953 before we began this type of briefing, there were 28 unexplained fatal accidents in jet aircraft in the Flying Training Air Force or 1 fatality every 13 days. In 1954 after 1 year's indoctrination of the program outlined there were only 8 unexplained fatalities, or 1 every 45 days. In 1955 there was only 1 every 72 days and in 1956 there were only 2 unexplained fatal accidents. Other factors such as supervision, instruction and maintenance undoubtedly have contributed to this improved safety record.

### RELATIVE HYPOGLYCEMIA

Wiggers<sup>1</sup> defined hypoglycemia as a progressive decrease in blood sugar characterized when it reaches the environs of 75 mg per cent by weakness, trembling, nausea and vomiting. Harrison and Fink<sup>2</sup> defined relative hypoglycemia as a metabolic disorder characterized by nervousness, weakness, palpitation, dizziness, dyspnea, arrhythmias and chest pain—occurring two or more hours after meals. These symptoms can usually be reproduced by insulin, relieved by the ingestion of glucose and prevented by dietary regulation (high protein, low carbohydrate). Blood sugar is found usually slightly subnormal or normal. These authors pointed out that there is a great variation in individual susceptibility, some patients tolerating blood sugars as low as 40 mg per 100 ml without symptoms, while others experience difficulty at 65 to 70 mg per 100 ml.

Diabetics experience insulin overdose manifestations with blood sugars at or above the normal range, an example of relative hypoglycemia. Of the 31 patients observed with sugar tolerance tests by Harrison and Fink, 2 had blood sugar levels below 50 mg per 100 ml, 7 had 50-59, 11 had 60-69, 7 had 70-79 and 1 patient

had 80 The rapid descent of the curve, as well as the minimum level, seemed significant The response to insulin in the reproduction of the symptoms was positive in 15 out of 18 patients tested and is regarded as a valuable diagnostic aid The response to treatment with a high protein, low carbohydrate diet proved one of the most useful diagnostic procedures

In treatment, the diet used by Conn<sup>8</sup> (low carbohydrate, high protein) was usually effective in contrast to high carbohydrate meals with intermediate feedings The high blood sugar produced by the latter regimen apparently produced excessive insulin production Conn and associates<sup>10</sup> pointed out that after a high protein meal, the blood sugar level is relatively stable because the protein is gradually converted to amino acids, which in turn are changed to glucose

From observation of certain low altitude "near accidents" in the Air Force, supported by a limited number of laboratory tests, the conclusion was reached that these accidents might have the etiologic component of relative hypoglycemia The following cases will serve to illustrate this possibility

### CASE REPORTS

**Case 1** A student pilot became unconscious while flying with an instructor at an altitude of 8,000 feet After the plane was landed by the instructor the Flight Surgeon studying the cause of the student's failure did a six hour glucose tolerance test, and at the end of three hours the blood sugar was reported as 53 mg per 100 ml

**Case 2** A young pilot flying solo in a jet plane reported blacking out for a short period at an altitude of only 1,700 feet On recovering he found himself at an altitude of only 200 feet but was able to make a safe landing This individual also was given a six hour glucose tolerance test, and at the end of three hours a low point of 63 mg per 100 ml was reported

**Case 3** A young pilot in a T-33, during a landing about 2100 hours neglected to turn on his landing lights and let his flying speed drop to below 100 knots He failed to take proper corrective measures and his plane stalled dropped 25 to 30 feet to the runway, bounced, and on the second contact with the ground, the landing gear collapsed The pilot was unhurt and the Accident Investigation Board found the accident due to hypoxia Subsequent inquiry from the Flying Safety Officer, however, gave the following information

"This pilot attended a banquet the night before and had a meal presumably a well balanced one at 1900 He did not get to bed until 0330 but arose at 0600 His breakfast consisted of a candy bar and a soft drink He flew with a student for approximately 1 hour and 10 minutes Between the time he landed and 1530 He had additional candy bars and soft drinks He slept 1 hour during the afternoon but prior to take off he had no food except another candy bar and another soft drink "

We considered that a blood sugar deficiency in these three cases contributed to these hazardous conditions. We believe that relative hypoglycemia may play a definite part in some of our aircraft accidents. Certain cases with symptoms due to hypoxia, hyperventilation, and relative hypoglycemia may occur separately or in combination, and the pilot will be more susceptible if he has skipped a meal or has had only a high carbohydrate meal two or more hours previously. In flight, the pilot is subjected to both mental and physical stresses and glucose is imperative for cellular utilization of oxygen, and hence the proper function of the central nervous system. If the pilot eats a high protein meal including eggs and meat, his blood sugar level would be maintained at good levels for a much longer period because as pointed out by Conn and co-workers, these proteins will be converted to amino acids, which in turn will be changed gradually to glucose. With such a diet the pilot is maintained from meal to meal at relatively safe blood sugar levels.

In the Spring of 1955, a visit was made to all of our pilot training bases and our students were interviewed to find out just how many of them were not eating properly before flying. It was discovered that over 50 per cent of our students were not getting up for breakfast. They consequently, were flying without an adequate breakfast, or with none at all, and laying themselves wide open for a pilot-error accident. This situation was discussed with the Commander of Flying Training Air Force and it was decided that something had to be done about it. In June 1955 we initiated a very intensive program to improve the eating habits of our young pilots. This was done by explaining to them and their wives the importance of a well balanced breakfast, lunch, and dinner. It was explained to them that the protein foods—eggs, meat, and milk—are the most important elements in breakfast and other meals, and it is these protein foods that hold the blood sugar level relatively high for a long period of time. Our headquarters also published a directive in which all of our flying students (cadets) as well as officers residing on the base, were required to eat at least two meals breakfast and lunch, at one of the base messes. At the same time, a small snack bar was established in each of our flight briefing buildings. These snack bars were simple affairs, containing a refrigerator and a small counter. The foods stored in the refrigerator were milk, fruit juices, and good sandwiches—meats of all kinds and cheese. We discouraged the use of doughnuts in these snack bars since they consist primarily of carbohydrate and fat which might contribute to overstimulation of the internal secretion of the pancreas. In fact we believe that the best part of the doughnut is the hole in the middle. The snack bars were not open in the morning until after students had taken off on their first flight for we did not want them to use this as a substitute for an ad

July 1957)

## FLYING SAFETY PROGRAM

943

equated breakfast. They were opened prior to the ending of the first flight so that students and instructors could get a bite to eat at a time when their blood sugar level could be expected to be at a comparatively lower level.

This program to improve the eating habits of our pilots has been in effect a little more than a year, and we have indications that it is succeeding. This is reflected in the accident rate. The accident rate for 1954 in Flying Training Air Force was 16.6, in contrast with the rate in 1955 which was 12. The reduction in 1955 occurred primarily in the latter part of the year, after the program had been initiated in June. The aircraft accident rate for the 6 month period was 10.8, which is considered low. In comparison, the aircraft accident rate for the rest of the Air Force, not including Flying Training Air Force, for 1955 was 23, or more than double the FTAF rate. The accident rate in 1956 was 10.4. Together with the reduction in the accident rate, we have had a reduction in the per cent of pilot error accidents, approximately 56, and in 1956 it was 47.2. Another indication is the fact that during the first 6 months after this program was started there was a 2 month period in which no fatalities occurred, the only 2 months since FTAF was organized in 1951 with no fatalities.

To all who are interested in studying the problems of hypoglycemia I make this recommendation: do not limit glucose tolerance tests to 2 or 3 hours. Carry them out to a full 6 hours. Abrahamsen and Pezet<sup>11</sup> pointed out that some cases of hypoglycemia may present completely normal glucose tolerance curves in 2 to 3 hours, but the curve may then descend to near shock levels in the fourth, fifth, or sixth hour.

### SUMMARY

There are three things that we in Flying Training Air Force have done which apparently have helped reduce our aircraft accident rate. They are (1) The initiation of the Physiological Near Accident Report in 1952. These near accident reports give far more information regarding accident causes than the fatal accidents reports, and could be used profitably in all Air Force training centers. (2) The education of our pilots regarding hyperventilation, which pointed out the symptoms and its dangers. (3) Our program for improving the eating habits of our student pilots.

There are many more questions that have to be answered about relative hypoglycemia and hyperventilation. It is believed that we have only scratched the surface. Our Flight Surgeons and our research laboratories are confronted with a definite challenge to obtain firm answers to these problems through the continued

co-ordination of clinical observations with fundamental investigation

## CONCLUSIONS

- 1 Two of the less obvious hazards for pilots in training are hyperventilation with hypocapnia and relative hypoglycemia
- 2 The Flying Safety Program in the Flying Training Air Force has shown a decided decrease in the number of aircraft accidents and near accidents with the recognition and prevention of these hazards
- 3 The future selection and evaluation of student pilots might well include the determination of their susceptibility to hyperventilation with hypocapnia and hypoglycemia

# GENITOURINARY TUBERCULOSIS

STEPHEN J. BERTE *Lieutenant Colonel MC USA*

**G**ENITOURINARY tuberculosis maintains a prominent position in the consideration of human tuberculosis because, in addition to the lungs, the genitourinary tract is one of the most frequent sites of clinically recognizable tuberculosis. The emphasis continues to be on pathogenesis and treatment. Evidence in the literature suggests that infection in the genitourinary tract is secondary to a focus elsewhere in the body. Usually this original focus is in the lungs, bone, or intestine.

Treatment is best considered in terms of the pre streptomycin era and the post streptomycin era. Before streptomycin sulfonamide (SM) was used in the management of tuberculosis, treatment was limited to surgical resection. At one time, it was believed that a diagnosis of unilateral renal tuberculosis should be considered concomitantly with immediate nephrectomy. The approach in the past was dependent upon diagnosing unilateral or localized disease and then performing radical surgery before the disease could become widespread and inoperable. Various radical surgical techniques for genital and renal tuberculosis have been devised in an attempt to reduce the relapse rate and mortality after a 5 year period. Long term studies varying from 3 to 14 years in both genital and renal tuberculosis have shown an overall treatment failure of approximately 50 per cent following operation. These failures include both relapse and death. In isolated reports a 70 to 80 per cent conversion rate was attained with operation alone. However, the latter studies were usually of less than 5 years' duration. All long term studies gave the patient a 50 per cent chance of relapse.

The era of antituberculous drugs has relatively recently come into its own. It is hoped that in future years these drugs, added to judicious surgical intervention, will materially reduce the morbidity in genitourinary tuberculosis. The following discussion is a general review of the literature in an attempt to reiterate the present day thinking concerning the pathogenesis and treatment of genitourinary tuberculosis.

## INCIDENCE AND SITE OF DISEASE

The reported incidence of genitourinary tuberculosis in 15,000 documented cases of tuberculosis of all types was 4 per cent.<sup>2</sup>

*From Valley Forge Army Hospital Phoenixville Pa.*

The over all ratio between males and females of tuberculosis of the urinary tract is approximately 3:1. The predominant age group having genitourinary tuberculosis falls within the third to fifth decade and the peak incidence occurs between the ages of 25 to 30 years, with a significant number of patients contracting the disease at age 50.

There has been a considerable amount of data accumulated relating to the presence of extragenitourinary tuberculosis occurring concomitantly with genitourinary tuberculosis. As will be seen in the following discussion renal tuberculosis always occurs secondarily to a focus of tuberculosis in some other organ. However, there are times when no other evidence of tuberculosis can be discovered other than genitourinary tuberculosis. Varying reports have shown pulmonary tuberculosis to be detectable in 30, 50, and 70 per cent of patients having tuberculosis of the seminal vesicles, prostate and epididymis. Osseous tuberculosis is also relatively frequently associated with genitourinary tuberculosis. From 15 to 24 per cent of patients with genitourinary tuberculosis also have clinical evidence of skeletal tuberculosis.

The question of unilateral or bilateral renal involvement has been debated much and the terms "good" kidney and "unilateral" renal tuberculosis have entered the literature. This subject has been studied extensively by analyzing large numbers of autopsy cases. It is believed from this type of data, that renal tuberculosis is initially bilateral. One may, however, find it necessary to make multiple serial sections of the kidney to demonstrate microscopic foci of tuberculosis. Some workers, in doing routine autopsies on patients who have died of pulmonary tuberculosis with and without signs and symptoms of renal involvement have demonstrated 100 per cent bilateral tuberculosis. It is suggested that the term unilateral renal tuberculosis be used as a clinical expression and should really imply unilateral demonstrable tuberculosis. Not infrequently microscopic foci in the opposite kidney may continue on to healing and scar formation and reach the inactive stage. On the other hand the so-called "good" kidney may demonstrate evidence of tuberculosis within a few years following a nephrectomy.

If a patient has tuberculosis of the genital organs the potentiality of the coexistence of urinary tuberculosis is great. Forty five to 80 per cent of cases of renal tuberculosis are associated with genital tuberculosis. Tuberculosis has been found in the prostate in 95.2 per cent of all patients having genital tuberculosis and the epididymis has been involved in 48.5 per cent. These data speak for themselves and en-

phsimize that in all cases of genital tuberculosis in the male, the prostate is almost always involved, either alone or in combination with the epididymis and seminal vesicles

Tuberculosis in the genital tract of the female is a much more difficult problem because the disease is less apparent. Most data on this subject are of an indirect nature but give some insight into the frequency of occurrence. Data have been available in studying a large group of women who died of pulmonary tuberculosis. Autopsy material reveals that genital tuberculosis has been found in 1 to 30 per cent of these cases. In making a study of sterile women, it has also been indirectly found that 5 to 12 per cent of these women have evidence of endometrial tuberculosis.

#### PATHOGENESIS AND PATHOLOGY<sup>4,5,6</sup>

**Renal Tuberculosis** This is usually a secondary manifestation of tuberculosis elsewhere in the body. It is believed that a tuberculous focus of infection must first exist in an extrarenal site. This site is usually in the lungs, however, osseous tuberculosis may account for a focus of infection leading to subsequent hematogenous infection of the kidneys. In the English literature, tuberculosis of the intestinal tract is given significant importance in this respect. The kidneys are, thus, first infected by the hematogenous route. A bacillemin is produced by the discharge of bacilli into the circulation by erosion of the blood vessel at the site of the extrarenal focus. As a result of the very rich blood supply to the kidneys, these organs are most frequently involved following the bacillemia. The initial lesions are usually bilateral, in the cortex of the kidneys, and frequently occur in proximity to the glomeruli. These small initial cortical lesions may be completely healed by scar formation or become encysted. A small cortical lesion may ulcerate into one of the renal tubules and give rise to bacilluria. Under these circumstances, pyuria may not be present and the only evidence of renal tuberculosis may be the presence of acid fast bacilli on culture of the urine. At this stage, urography will also be normal. The initial lesions in the stago, urography will also be normal. The initial lesions in the cortex may be nodular or miliary, depending on the magnitude of seeding of the kidney from the distant foci. The caseocavitary type of lesion in the kidney is more important from the point of view of making a clinical diagnosis. These latter lesions frequently occur in the renal papillae as a result of spread from cortical lesions. The cortical foci spread either directly or via the lymphatics to the pyramids and give rise to definite lesions in the papillae where necrosis and extension occur. The initial lesion in the renal papillae may consist of one or more tubercles. These tubercles coalesce and extend into the papillary ducts and caseation occurs. From this point, sloughing into the minor calyx eventually occurs and produces

948 bacilluria, pyuria and hematuria. The hematuria may be microscopic or gross, depending on the size of the vessel eroded. There are several factors existing in the kidney which predispose to local spread within the tissue. Direct local spread and spread via the lymphatics have been mentioned. Tuberculous endarteritis or occlusion and thrombosis of an artery produced by the pressure of local tubercles may lead to a localized area of devitalized tissue in the kidney. Such devitalized tissue is a fertile area for the spread of tuberculosis. In addition one of the papillary ducts may be occluded by the process and this would encourage a retrograde growth of the organisms behind the point of obstruction. If there is a considerable amount of vascular thrombosis involving the renal arterioles, the kidney may be converted to a small contracted fibrotic organ.

The tuberculous process having invaded the minor calyx, will next extend to the adjacent major calyx and frequently convert the latter into a tuberculous cavity. The neck of the calyx may be closed and pyuria and bacilluria may no longer be present in the urine. The neck of the calyx may also be open intermittently producing only periodically positive urinoanalyses. This process in the renal calices usually develops slowly. However, it may take several months or several years for a spread to the lower urinary tract to occur. Nevertheless, the pelvis of the kidney and the ureter are the next areas to be affected by the tuberculous process. In the renal pelvis, contraction and ulceration occur. This may cause extensive shrinking of the kidneys due to scar formations. Invasion of the ureters and the submucosa and muscularis. The lesions in the ureters are usually small and result in abundant scar formation which may cause obstruction and further increase in the disease process above the area of obstruction. At times the ureter may be completely closed by stricture and produce what is known as auto-nephrectomy. This results in a small contracted, fibrotic non-functioning kidney containing tuberculous foci of infection.

**Tuberculosis of the Bladder** During the course of renal tuberculosis the urinary bladder sometimes becomes infected. There are several types of involvement in the bladder. Frequently, there are small yellow tubercles of a pale nature with a surrounding angry red areola which occur most commonly about the ureteral orifices in the bladder but are not necessarily always limited to these areas. The yellow tubercles may be absent from the bladder mucosa and the disease may present itself as a patchy red cystitis without tubercles. This is usually seen about the base of the bladder and sometimes on the anterior wall. Less frequently there may be more extensive lesions of the bladder in which the whole thickness of the bladder wall is involved without the presence of visible tubercles. There is usually a

progressive ulceration. This type of lesion has been described in the literature as localized panmural tuberculous cystitis.<sup>\*</sup> It is seen as a localized, granulomatous, fungating lesion involving the anterior wall of the bladder and usually about the size of a half dollar. This type of lesion tends to be more refractory to treatment. It is prone not to heal following nephrectomy as do other simpler lesions of a patchy or nodular nature involving the mucosa and submucosa. With panmural tuberculous involvement, the remaining bladder may look entirely normal and subtotal cystectomy appears to be the only successful means of curing this type of lesion.

**Genital Tuberculosis.** In the male, genital tuberculosis is thought always to occur secondary to urinary tuberculosis. Primary hematogenous tuberculous seeding of the genital organs in the male has theoretical possibilities but all indications strongly suggest that genital tuberculosis is most always secondary to urinary tuberculosis. The urinary tuberculosis may, however, as stated before, be in the form of asymptomatic renal disease manifested only by bacilluria with or without pyuria. As has been stated, over 95 per cent of patients with genital tuberculosis have involvement of the prostate.<sup>\*</sup> The prostate may contain firm nodules or be enlarged with soft caseous foci. Following prostatic involvement from the urinary tract, the infection may be spread via the ejaculatory duct to the seminal vesicles and to the vas deferens. Involvement of the seminal vesicles and vasa may be in the nature of tubal thickening or a nodular type of beading. By extension of this same process the epididymis becomes involved. The most frequent site of involvement is the tail of the epididymis which may be enlarged and swollen. As the disease progresses, it may become soft and caseous and involve the entire testicle. The process may eventually extend to the scrotum, thus involving the whole area in a caseous mass which may rupture exteriorly forming a fistulous tract.

Genital tuberculosis in the female differs in pathogenesis and pathology, primarily because of anatomic differences. In the male, genital tuberculosis is believed to be a descending infection from an infection higher in the urinary tract, originating in the kidneys. Ascending infections from the lower urinary tract or genital organs to the kidney is believed to be unlikely in the male. Similarly, retrograde infection is not believed to occur in the female, that is, tuberculosis of the external genitalia is not likely to spread in a retrograde fashion to the pelvic organs. Conversely, urinary tuberculosis in the female is thought to be an unlikely cause of tuberculous involvement of the uterus, tubes, and ovaries. Female genital tuberculosis involving these organs is therefore a result of hematogenous dissemination. Genital tuberculosis in the female may also be secondary to generalized peritoneal and pelvic tuberculosis. This type of tuberculosis

bacilluria, pyuria, and hematuria. The hematuria may be microscopic or gross, depending on the size of the vessel eroded. There are several factors existing in the kidney which predispose to local spread within the tissue. Direct local spread and spread via the lymphatics have been mentioned. Tuberculous endarteritis or occlusion and thrombosis of an artery produced by the pressure of local tubercles may lead to a localized area of devitalized tissue in the kidney. Such devitalized tissue is a fertile area for the spread of tuberculosis. In addition, one of the papillary ducts may be occluded by the process and this would encourage a retrograde growth of the organisms behind the point of obstruction. If there is a considerable amount of vascular thrombosis involving the renal arterioles, the kidney may be converted to a small contracted fibrotic organ.

The tuberculous process, having invaded the minor calyx, will next extend to the adjacent major calyx and frequently convert the latter into a tuberculous cavity. The neck of the calyx may be closed and pyuria and bacilluria may no longer be present in the urine. The neck of the calyx may also be open intermittently, producing only periodically positive urine analyses. This process in the renal calices usually develops slowly. However, it may take several months or several years for a spread to the lower urinary tract to occur. Nevertheless the pelvis of the kidney and the ureter are the next areas to be affected by the tuberculous process. In the renal pelvis contraction and ulceration occur. This may cause extensive shrinking of the kidneys due to scar formations. Invasion of the pelvis and ureters occurs at first in the mucosa and then involves the submucosa and muscularis. The lesions in the ureters are usually small and result in abundant scar formation which may cause obstruction and further increase in the disease process above the area of obstruction. At times the ureter may be completely closed by stricture and produce what is known as auto-nephrectomy. This results in a small, contracted, fibrotic, non-functioning kidney containing tuberculous foci of infection.

**Tuberculosis of the Bladder.** During the course of renal tuberculosis the urinary bladder sometimes becomes infected. There are several types of involvement in the bladder. Frequently, there are small yellow tubercles of a pale nature with a surrounding angry red areola which occur most commonly about the ureteral orifices in the bladder, but are not necessarily always limited to these areas. The yellow tubercles may be absent from the bladder mucosa and the disease may present itself as a patchy red cystitis without tubercles. This is usually seen about the base of the bladder and sometimes on the anterior wall. Less frequently, there may be more extensive lesions of the bladder in which the whole thickness of the bladder wall is involved without the presence of visible tubercles. There is usually a

Symptoms of genital tuberculosis in the male depend on the extent and location of the disease. In prostatic involvement, symptoms may be absent and discovery may depend entirely on physical examination. However, there may be dysuria or obstruction to the urinary flow by compression of the urethra or involvement of the urethra by the tuberculous process.<sup>11</sup> On rare occasions, stricture of the posterior urethra occurs, which can give rise to all the symptoms associated with benign prostatic hypertrophy and urinary retention. Symptoms of tuberculous involvement of the seminal vessels and the vas deferens may not be present. Involvement of the epididymis, however, may produce acute symptoms with pain and swelling, or there may be no symptoms whatsoever. The first indication of disease in the area may be the rupture of a caseous area through the scrotal skin causing discharge of caseous material following slight trauma.<sup>12</sup>

In female genital tuberculosis, symptoms have a tendency to be lacking. Any female, however, with symptoms of salpingitis who is virgin or who is free from venereal disease or postabortive infection should be strongly suspected of having genital tuberculosis. Amenorrhea may be present, but, of course, there are many other conditions that may produce this symptom.<sup>7</sup>

#### PHYSICAL SIGNS

In renal tuberculosis, physical signs are usually absent. The tuberculous kidney may not be palpable or tender.<sup>4</sup> Only on rare occasions may the kidney be enlarged to the extent that it may be palpable and slightly tender. Involvement of the prostate and seminal vesicles by tuberculosis may be manifested by swelling, tenderness, nodules, softening, or fluctuation. In the acute form of tuberculosis of the epididymis, there may be a tender swelling in the tail of the epididymis, usually with sparing of the testicle. The vasa may also be tender. There is not infrequently an associated hydrocele. As the process gets older there develops a firm or soft, perhaps even fluctuant or "doughy," swelling in the tail of the epididymis. With long standing disease of a more extensive nature, the testes may be involved in this swollen mass. Beadlike sclerosis may be present in the vasa. Involvement of the epididymis, vasa, or seminal vesicles on one side may also be associated with tuberculous infection on the contralateral side, even though this may be difficult to discover clinically.<sup>5, 6</sup>

Diagnosis of pelvic tuberculosis in the female is extremely difficult without definite symptoms and palpable lesions. In most patients with palpable abnormalities in the pelvis, the diagnosis is made only after pathologic study.<sup>7</sup> It is frequently not suspected when there is no other evidence of tuberculosis in the body. Even in the presence of extragenital tuberculosis, palpable pelvic masses or abnormalities may lead to the suspicion

will not be considered in this discussion inasmuch as it is a complication of generalized tuberculosis of the pelvis and peritoneum. The fallopian tubes are most frequently involved first in the "seeding" from a distant focus of tuberculosis. Initial involvement of the tubes is sometimes indistinguishable from recurrent gonorrheal infection, even at the time of surgery. The tubal tissue involved is characterized by its pallor. There is a tendency to marked thickening and induration of the fallopian tubes. Calcification is not infrequent. In approximately half of the cases, the fimbriated end of the tubes may be opened, and at the time of examination, caseous material may be expressed from the lumen. Within the mucosa of the tubes, there may be hyperplasia and thickening with tubercle formation and ulceration. From the tubes, the process is believed to extend in both directions to the uterus and to the ovaries. The uterus itself may rarely be involved initially. The chief involvement is in the endometrium. Tubercles are present but are usually small and difficult to recognize except at microscopic examination. The disease in the endometrium is characterized by ulcerations and caseous lesions. At times multiple tubercles may be the chief lesions. When the ovaries are involved, tubal ovarian abscess is seen which is not prone to spontaneous healing. The cervix is frequently spared but may be involved in approximately 5 per cent of cases of genital tuberculosis in the female. Cervical tuberculosis is usually associated with involvement of the tubes and uterus. It may have a papillary form presenting a cauliflowerlike growth which may grossly be in the form of carcinoma. Tuberculosis of the external female genitalia, the vulva and vagina, are the most infrequent site of tuberculosis of the skin and there is a great tendency to papillary growth and ulceration which may be related to the presence of more moisture in this area.

### SYMPTOMS

Urinary tuberculosis may produce no symptoms. Pyuria and bacilluria may be the only indications of a lesion. When symptoms are present, urgency and frequency of urination resulting from tuberculous cystitis secondary to renal tuberculosis is frequently noted. True renal colic may be encountered which is due to the passage of caseous material, blood clots or bits of discharged calcified material into the ureter. A dull constant nagging flank pain over the affected kidney is a frequently described symptom which is thought to be secondary to hydro-nephrosis produced by ureteral stricture. The patient may occasionally complain of gross hematuria as a result of the tuberculous process eroding a medium sized vessel. On rare occasions the picture of acute pyelonephritis or acute pyelitis may be produced including acute pain, chills and fever.<sup>10</sup>

disease. On certain occasions a sominal vesiculogram may be performed.

In female genital tuberculosis, laboratory or diagnostic procedures are limited to three major steps (1) Dilation of the cervix with curettage of the uterine endometrium may be performed in order to obtain a biopsy and material for culture. This material may also be used for guinea pig inoculation. (2) Menstrual blood may also be cultured. Some authors advocate this procedure as a routine in all female patients with pulmonary tuberculosis. The feasibility of such a wide scale study, however, has its limitations. (3) Culdosecopy grants direct visualization and, under special circumstances, may lead one to suspect pelvic tuberculosis. Culdosecopy may be of particular importance in the follow up study of patients with known pelvic tuberculosis following long term adequate therapy.

### THERAPY

Prior to the streptomycin sulfate (SM) era, therapy for genitourinary tuberculosis was limited to surgical intervention for all resectable lesions and conservative and sanatorium care for nonoperable lesions. For unilateral caseous tuberculosis of the kidney, nephrectomy was performed. For bilateral renal tuberculosis, conservative therapy was used and the prognosis was always poor. Even with nephrectomy for unilateral disease, there were only slightly more than 50 per cent of patients alive five years after nephrectomy. Genital tuberculosis, likewise, was treated by radical surgical resection when feasible. The introduction of SM and other allied drugs to the treatment of genitourinary tuberculosis added a new light and a new hope to this hitherto fore unfavorable disease. Up until 1950, the use of SM was recognized as an excellent adjunct to genitourinary surgery.<sup>23</sup> It limited the formation of fistulas following surgery, and permitted the use of localized resection rather than nephrectomy.<sup>14-16</sup>

Between 1950 and 1952, the response of genitourinary tuberculosis to many combinations of dosage of SM and para-aminosalicylic acid (PAS) given for periods of three to four months were studied.<sup>17-21</sup> These studies indicated that minimal lesions all responded well initially, but that advanced lesions responded poorly. The recommendation at this time was to resect all lesions that were greater than minimal.

In 1952, Lattimer and his group<sup>14</sup> emphasized that 55 per cent or more of patients developed relapses within two years, when given short courses of SM and PAS, and proposed that treatment be continued for from one to three years. Minimal lesions were treated with drug therapy alone, but the tendency to treat all lesions other than minimal renal lesions with drugs plus surgery still remained.

of genital tuberculosis, but its diagnosis will usually depend on laboratory data, operative specimens or perhaps culdoscopy

### DIAGNOSTIC PROCEDURES

Routine urinalyses should be performed with particular attention to the presence of pyuria, hematuria, and albuminuria. The presence of pus cells in the urine is the most frequent abnormality. Hematuria is not infrequent and is usually microscopic. The occurrence of gross hematuria depends on the size of the vessel eroded by the tuberculous focus. Albuminuria is not usually seen until the disease becomes more advanced. A search for tubercle bacilli should be made on a stained smear of concentrated sediment, by culture, and guinea pig inoculation. It is to be remembered that the only laboratory finding of renal tuberculosis may be the presence of bacilluria. Pyelography, both excretory and retrograde, is one of the major procedures used in the clinical diagnosis of renal tuberculosis. There has been much discussion about the advantages of either method. Some authors state that the excretory pyelogram is usually not as completely satisfactory as the more complete filling obtained with the retrograde pyelogram. However, no dogmatic statement should be made and both methods should be utilized in each patient. An excretory pyelogram will give one an indication of the function of each kidney and may be followed by retrograde pyelography for a more complete study after a relatively good indication of the extent of the disease has been obtained. Lattimer and associates<sup>10</sup> classified renal tuberculosis into five main groups, according to the abnormalities seen on the pyelogram. They designate group 0 as renal tuberculosis manifested only by the presence of bacilli in the urine and with negative pyelographic findings. Grade 1 demonstrates only slight pyelographic abnormalities plus bacilluria. Grade 2 must have definite changes on the pyelogram consistent with tuberculosis involving one calyx plus bacilluria. Grade 3 has exactly the same criteria except that the pyelogram must show involvement of two calices. Grade 4 must show three or more calices involved on the pyelogram. Hydronephrosis, secondary to tuberculosis and specifically secondary to urethral stricture, is classified separately.

Cystoscopy should be performed in all cases of proven renal tuberculosis. Separate urine specimens should be taken from each ureter and from the bladder for microscopic examination and for a search for bacilli. In male genital tuberculosis, laboratory procedures are for all practical purposes, limited to the examination of the urine for the presence of tubercle bacilli. Some authors advocate prostatic massage to collect samples for cultural studies. Others, however, believe that this process is unwise because of the possibility of dissemination of the

disease. On certain occasions a seminal vesiculogram may be performed.

In female genital tuberculosis, laboratory or diagnostic procedures are limited to three major steps: (1) Dilatation of the cervix with curetting of the uterine endometrium may be performed in order to obtain a biopsy and material for culture. This material may also be used for guinea pig inoculation. (2) Menstrual blood may also be cultured. Some authors advocate this procedure as a routine in all female patients with pulmonary tuberculosis. The feasibility of such a wide serologic study, however, has its limitations. may be made, however, to summarize the present treatment of genitourinary tuberculosis. Surgical intervention should not be performed in genitourinary tuberculosis in the presence of active or unstabilized extragenital tuberculosis. An effort should be made first to control and arrest the extragenital focus. The genitourinary tract should be re-evaluated then, in reference to the indications of therapy. By doing this, one will be able to derive knowledge by observing the response of the genital and extragenital focus under chemotherapy. In the absence of extragenital foci or in the presence of inactive extragenital foci, minimal lesions in the genitourinary tract may be treated with chemotherapy alone. Lesions other than minimal in nature have until recently seemed to require surgical intervention. However, there seems to be some indication that many moderately advanced and some far advanced lesions may respond satisfactorily to long term chemotherapy.

The present accepted drug regimen in genitourinary tuberculosis consists of 1 gram of SM every third day, 300 mg of INH daily, and 12 grams of PAS daily. Upon the recommendations of Doctor Lattimer, this therapy offers the best results to date when continued for at least 24 months. Patients with minimal renal lesions and normal findings on pyelography have had rapid clinical and bacteriologic reversal and have done well on only 1 year of this regimen. Recent reports<sup>24</sup> suggest that, in addition to PAS, INH in doses of 16 mg per kilo per day (with from 50 to 100 mg of pyrazinone), and SM daily for at least 3 months may further improve the chemotherapeutic results in tuberculosis.

#### SUMMARY

Genitourinary tuberculosis is a frequent extrapulmonary site of tuberculous infection. *Mycobacterium tuberculosis* may be disseminated via the blood stream from a primary extragenital focus and trapped by the richly vascular kidneys. Secondary foci of infection may then spread in a retrograde fashion to the genital organ. Tuberculous infection of the renal and genital organs of the female occurs by the hematogenous route.

Before and after the chemotherapeutic era and up to 1956, surgical resection was instrumental in all forms of treatment of genitourinary tuberculosis except minimal lesions. Present-day experience indicates that the pendulum may be swinging away from radical surgical excision. Two years of triple drug therapy (streptomycin sulfate, isoniazid, and para-aminosalicylic acid) without surgical intervention, are advocated for most genitourinary tuberculous lesions that show a response to therapy. Many patients with far advanced lesions may do better than previously suspected on long term drug therapy alone. Operative procedures should be reserved for those with the more advanced stages of the disease and based upon individual case circumstances.

# TUBERCULIN SENSITIVITY AMONG ARMY CHILDREN

THOMAS A. HANSON, *Captain MC USA*

MERCEDES FISCHER *Major ANC USA*

THE SUCCESS of the newer drugs and surgical methods in decreasing tuberculosis in the United States should bring new emphasis on the tuberculin skin test for detecting infections in children. Myers and associates<sup>1</sup> demonstrated that in Minnesota the incidence of positive reactors among school children has gradually declined from 70 per cent in 1916 to 4 per cent in 1956. This is typical of the trend throughout the country.

It was our impression that tuberculosis is more prevalent in dependent children of Army personnel than in the general population. To test the validity of this idea and elucidate the factors which might account for such a difference, a survey study employing the tuberculin skin test was carried out in the spring of 1956 at Fort Lewis, a typical Army post located in western Washington.

## MATERIAL AND METHOD

In March 1956 a questionnaire requesting parental consent to tuberculin testing was given to 1,245 school children, aged 5 to 14 years, at the Fort Lewis and Dupont district schools. The children selected for study were all military dependents. One child who had been vaccinated with BCG was not included. A preliminary education program was presented at a Parent Teachers Association meeting with assistance from the Pierce County Tuberculosis Association, and was responsible in part for the excellent response. Only 39 declined the test. Many slips were not returned, and 49 agreed to the test but were either absent during the reading period or transferred before the program was in progress. A total of 1,041 dependent children of Army personnel were tested.

A short history was taken for each child, to determine any who had had known or suspected exposure to tuberculosis or

---

in a per cent positive of 8.5 as compared with 7.3 for the "United States only" group (table 3). The slightly increased incidence of tuberculin sensitivity among American born Army children who have lived in other countries is not significant and could well be due to chance alone or to inaccuracies in the biographical data submitted by the parents.

TABLE 1 *Results of tuberculin skin tests on 1 041 dependent children of Army personnel*

School grade	Number tested	Positive reactors		Negative reactors	
		Number	Per cent	Number	Per cent
Kindergarten	145	11	7.6	134	92.4
First	146	6	4.1	140	95.9
Second	176	13	7.4	163	92.6
Third	148	7	4.7	141	95.3
Fourth	107	10	9.3	97	90.7
Fifth	71	6	8.5	65	91.5
Sixth	78	14	17.9	64	82.1
Seventh	74	14	18.9	60	81.1
Eighth	54	9	16.7	45	83.3
Ninth	42	14	33.3	28	66.7
Total	1 041	104		937	

TABLE 2 *Results of tuberculin skin tests tabulated according to whether or not subjects had lived overseas*

	Positive reactors		Negative reactors		Total number
	Number	Per cent	Number	Per cent	
United States only	29	7.3	367	92.7	396
Overseas	75	11.6	570	88.4	645
Total	104		937		1 041

Includes native born children from Panama, Philippine Islands, and Puerto Rico.

The survey was responsible for the detection of 1 new case of active, moderately advanced, pulmonary tuberculosis in a parent. There were 6 instances of healed calcified foci in adults and children, and 1 case of presumably arrested, minimal, pulmonary tuberculosis in a child, age 9. In 4 children there was a clear cut association with tuberculosis in a relative. In 2 cases

families living in Japan had discovered servants with pulmonary tuberculosis. Multiple positive reactors were found in 11 families accounting for 25 cases. Twenty-one of the latter came from 9 families native to Panama, Puerto Rico, and the Philippine Islands. These 9 families contributed 20 per cent to the total group of sensitized children.

TABLE 3 Results of tuberculin skin tests tabulated according to whether or not subjects had lived overseas

	Positive reactors		Negative reactors		Total number
	Number	Per cent	Number	Per cent	
United States only	29	7.3	367	97.7	396
Overseas	49	8.5	530	91.5	579
Total	78		897		975

Excludes native-born children from Panama, Philippine Islands, and Puerto Rico

### DISCUSSION

The declining rate of positive reactors in children seems to indicate that fewer children are being exposed to tuberculosis than formerly. Because of this it becomes even more important and productive to seek out those individuals who are tuberculin positive not only to find active cases but also so that this small group can be carefully observed throughout the years to come for earliest signs of reactivation. To emphasize the usefulness of early detection Myers and associates stated, "Periodic examination at least annually will permit diagnosis of 95 per cent of evolving chronic pulmonary lesions while they are minimal, before they produce symptoms and usually before they are contagious." Furthermore it is possible that drug therapy will be found of value in early treatment of recent converts even though no evidence for progressive disease exists. This question is now being debated.<sup>2, 3</sup>

Intradermal tuberculin testing on civilian school children has demonstrated varying rates of sensitivity depending on ages of subjects tested and locality in which the tests were done. In Kansas City the rate ranged from 1.3 to 3.1 per cent in kindergarten classes depending on the sector of the city—the lower rates being in the better housing and higher income areas.<sup>4</sup> In New York City large numbers of high school children have been tested and show an exposure rate of from 5.7 per cent in the 13 year old group to 19.4 per cent in the 17 year old group.<sup>5</sup> This is considerably lower than the rates in our 11 to 14 year-old subjects.

In Pittsburgh the rate for 537 children, ages 1 to 16, consecutively hospitalized at the University of Pittsburgh and Children's Hospital during parts of 1950 and 1951, was 0.6 per cent. Our rural Minnesota counties, testing during 1946 and 1947, demonstrated a low rate of 2.7 per cent in children of ages 6 through 14. This group compares closely to ours in age spread, but its rate of tuberculin sensitivity is much lower than our rate of 10 per cent.

Certain types of information obtainable from studies such as this may be of value in answering questions regarding changing public health problems with tuberculosis. There is a need to know just what proportion of our school children are not being protected, what areas show the greatest exposure rates, and what is the cost involved in case finding through skin testing and mass chest surveying programs.

In a population of Army personnel and their families, which is largely proscreened by frequent physical examinations, the now case rate for tuberculosis would be expected to be low, as was true in our study. We have, however, demonstrated that dependent children who come to the United States as native born Filipinos, Puerto Ricans, or Panamanians represent a group where the positive reactor rate is disproportionately high (26, or 33.4 per cent, of an estimated total of 66 subjects). This group, along with other previously infected children, represents a reservoir of possible focus of infection if the disease evolves into open lesion tuberculosis. Physicians concerned with the health of dependents should intensify their efforts to control tuberculosis through frequent use of skin testing programs with long term follow up and parent education regarding the need for periodic roentgenographic examination of the chest of previously infected children.

#### SUMMARY

One thousand and forty one dependent school children of Army personnel stationed at Fort Lewis, Wash., were screened for tuberculin sensitivity by skin testing. The rate of positive reactors was 10.0 per cent, which is higher than in comparable civilian groups reported by others.

Of the children who had been overseas, 11.6 per cent had positive reactions as compared with 7.3 per cent for those who had lived only in the United States; however, 66 native-born children from Puerto Rico, Panama and the Philippine Islands accounted for 23 per cent of the positive reaction.

The ~~screen~~ was responsible for the detection of one new case of pulmonary tuberculosis in a parent.

**ACKNOWLEDGMENT** The tuberculin used in this study was supplied by the National Tuberculosis Association of Pierce County Wash.

# TREATING TUBERCULOSIS IN A MILITARY HOSPITAL

RICHARD M. BURKE, Lieutenant Colonel, U.S. Army  
JAMES A. WIER, Colonel, U.S. Army

**T**HE INTRODUCTION of specific drug treatment brought a new era from which a new treatment is emerging. A review of the management of a large tuberculosis service should reflect the management now evolving. With this in mind, the tuberculosis section of this hospital for the past few years has been studied. Some of these have been previously briefly presented elsewhere. This material will be presented as to the therapy and differences between military and treatment of tuberculosis.

This hospital treats three groups of patients: (1) military personnel (Army and Navy), (2) dependents of military personnel, and (3) beneficiaries of the Veterans Administration. The military patients are largely young men with recent disease. The civilian dependents are mainly wives of service men, about a third of whom are foreign born. All stages of the disease are represented in the Veterans Administration patients. There are older individuals with advanced, long standing disease.

During 1955, 932 patients were discharged from the tuberculosis section. Of these, 100 per cent were found to be nontuberculous and 50 per cent had inactive tuberculosis, while 79.6 per cent were considered to have active disease. Of the patients with active tuberculosis, 69.9 per cent had pulmonary disease, 5.9 per cent had pleural effusion alone, and 4.2 per cent had extrapulmonary tuberculosis. In those with active pulmonary tuberculosis, the disease was minimal in 27.8 per cent and far advanced in 23.2 per cent as compared with 18.5 per cent minimal and 30.1 per cent far advanced in 1952 (table 1).

The disposition of the patients is shown in table 2. Of the military patients, 46.8 per cent were transferred to Veterans

From Fitzsimons Army Hospital, Denver, Colorado. Dr. Burke is now Director, Division of Tuberculosis Control, State Department of Health, Oklahoma City, Oklahoma.

Administration hospitals to continue treatment, while the remainder with a few exceptions, were treated at this hospital until maximum results were obtained. Irregular discharges of

military patients (those in which the patient leaves against medical advice with inadequately treated active disease) were in

significant because of Army disciplinary powers. This is in sharp contrast to the Veterans Administration patients in this hospital, with an irregular discharge rate of 30.6 per cent, and to the average rate for irregular discharges of tuberculosis patients in Veterans Administration hospitals throughout the United States of about 40 per cent. The civilian dependent irregular discharge rate was 8.8 per cent, and those discharged with maximum hospital benefit reached 82.0 per cent as compared with 55.3 per cent in 1952.

### TREATMENT

**Hospitalization** The criterion for approved discharge is negative sputum, cavity closure, and roentgenographic stability for from four to six months. The time required to achieve this goal averaged 12 months for those with minimal disease, 15 months for those with moderately advanced disease, and 15 plus months for those with far advanced disease.

Available data for 1955 show a reduction in the period of hospitalization because of changes in policy. For example, military patients are now allowed to complete the last three to six months of their prescribed drug therapy while on convalescent leave, rather than remain under hospital supervision for this phase of the treatment. Nonmilitary patients are allowed to return home when conditions are suitable, once their sputum is negative for *Mycobacterium tuberculosis* and a noncavitary pulmonary lesion is stable in serial roentgenograms for at least three months.

The amount of physical activity allowed while awaiting stability of the disease is slowly being modified. The trend has been toward less bed rest, but as yet there has been no radical change in policy. Of great interest is a project started at this hospital in July 1954. It is a study designed to compare at random patients following the conventional rest program with patients on an in-hospital ambulant program. Patients in the latter group follow no rest periods and can be up and about the ward and grounds of their building at will. Thus far, no appreciable difference has been noted in the response of the two groups as measured by sputum conversion and roentgenographic evidence of clearing of the lung lesions, but morale of the ambulant group is much better. Further, this group is permitted to start educational and rehabilitation training shortly after admission.

**Chemotherapy** The length of chemotherapy has been constantly increasing since the introduction of combined drug treatment. All patients with active disease are given drugs for a minimum of 12 months whether the lesion is glandular, renal, pulmonary,

or of bone. One of the following drug combinations is commonly employed: 300 to 450 mg of isoniazid (INH) daily with 12 grams of para-aminosalicylic acid (PAS) daily, INH and 2 grams of streptomycin sulfate (SM) every three days, or PAS and SM.

The simultaneous use of three drugs was found to have no advantage over dual therapy. Ordinarily isoniazid, the most effective of the antituberculosis drugs, was included in the therapy of previously untreated patients. The use of isoniazid alone in early reinfection tuberculosis has been advocated by a few physicians but no patients were placed on such a regimen. When treating primary tuberculosis in infants on the strength of only a positive tuberculin test, isoniazid alone was sometimes employed.

Isoniazid at conventional dosage rarely caused peripheral neuritis. With higher dosage it appeared in about 5 per cent of the patients. Pyridoxine hydrochloride is employed to prevent this complication. PAS is still a difficult drug to administer because of the gastro-intestinal irritation produced in some patients. The freshly prepared solution of sodium PAS is used. More acceptable preparations in stable powder form seem to be in the making. Eighth nerve toxicity from streptomycin with conventional dosage was an infrequent complication. Periodic audiograms are done on all patients, but vestibular studies are no longer routinely performed.

The re-treatment case with resistance to all three drugs is a difficult problem. The continued use of INH in such patients was favored despite the predominance of resistant strains. As a companion drug viomycin sulfate was adequate. Pyrazinamide was used with caution as its hepatotoxicity is still not a settled question. Oxytetracycline is a satisfactory short term substitute for PAS and was employed occasionally.

How effective is drug therapy in converting the sputum? First it is to be noted that the per cent of patients treated to maximum hospital benefit (1955) who had a positive sputum sometime during their treatment was: military 69 per cent, veterans, 52 per cent and civilian dependents 63 per cent. In a special study of 200 military patients treated to maximum hospital benefit (1953-1954) it was found that in the majority a positive sputum is converted in the first two months. After six or more months of treatment only 10 patients still had a positive sputum. It is of further interest that pulmonary operations were performed on 50 per cent of these same patients. *Mycobacterium tuberculosis* was found in the surgical specimen in all except five.

**Temporary Collapse.** Artificial pneumothorax was abandoned at this hospital in 1952 and artificial pneumoperitoneum two years

Inter (fig 1) Whether the infection is in the lung or other tissues, the response to drug therapy seemed much the same. The added benefits ascribed to lung collapse are not very convincing and would appear to be outweighed by the potential complications and inconvenience to the patients.

Figure 1 Trend in surgical procedures used in the treatment of patients with pulmonary tuberculosis 1947-1955

**Surgery** Table 3 shows a 100 per cent increase in pulmonary resections between 1952 and 1954. In 1954, 51 per cent of the patients treated to the inactive stage of the disease had resections, largely segmental. The number and type of procedures performed are listed in table 4. Figure 1 indicates that the peak year for pulmonary resections was 1954. The decline since then has resulted largely from a decrease in segmental resections for small caseonodular residuals (under 2 cm in diameter) and for upper lobe segments that are contracted, fibrotic, and often bronchiectatic but without large nodular residuals. This changing attitude is prompted by the minimum activity often seen in the surgical specimens plus an increasing confidence in the adequacy of long term drug therapy with isoniazid. Furthermore, while the mortality is low, the morbidity following resections has been sufficiently high to invite more conservatism. It is to be pointed out, however, that it appears likely that proportionately more resections will continue to be recommended for career soldiers than for civilian patients until follow up studies have been com-

or of bone One of the following drug combinations is commonly employed 300 to 450 mg of isoniazid (INH) daily with 12 grams of para aminosalicylic acid (PAS) daily, INH and 2 grams of streptomycin sulfato (SM) every three days or PAS and SM

The simultaneous use of three drugs was found to have no advantage over dual therapy. Ordinarily isoniazid the most effective of the antituberculosis drugs, was included in the therapy of previously untreated patients. The use of isoniazid alone in early reinfection tuberculosis has been advocated by a few physicians but no patients were placed on such a regimen. When treating primary tuberculosis in infants on the strength of only a positive tuberculin test isoniazid alone was sometimes employed.

Isoniazid at conventional dosage rarely caused peripheral neuritis. With higher dosage it appeared in about 5 per cent of the patients. Pyridoxine hydrochloride is employed to prevent this complication. PAS is still a difficult drug to administer because of the gastro intestinal irritation produced in some patients. The freshly prepared solution of sodium PAS is more acceptable preparations in stable powder form seem to be in the making. Eighth nerve toxicity from streptomycin with conventional dosage was an infrequent complication. P audiograms are done on all patients but vestibular P no longer routinely performed.

The re treatment case with resistance to all the difficult problem. The continued use of INH was favored despite the predominance of resistance. A companion drug viomycin sulfato was added. Viomycin was used with caution as its hepatotoxicity was a question. Ox tetracycline is a satisfactory question. Ox tetracycline is a satisfactory for PAS and was employed occasionally.

How effective is drug therapy in comparison with surgery? It is to be noted that the per cent of hospital benefit (1955) who had a permanent cure in their treatment was military 90 per cent and civilian dependents 70 per cent of 200 military patients treated (1954). It was found that in the first two years of treatment only 10 patients had a permanent cure. Further interest that 10 per cent of these same patients in the surgical series

Temporary Collep  
this hospital in

pleted This is because present figures suggest a lower reactivation rate for the resected patients<sup>7</sup>

### DEATHS

There were 17 deaths in 1955 or 2.2 per cent of the 790 tuberculous patients, as compared with 35 deaths in 1,184 tuberculous patients (3.0 per cent) in 1952. The various causes of death are detailed in table 5. No patient died of progressive tuberculosis. Most deaths resulted from pulmonary fibrosis, emphysema, or hemorrhage secondary to long-standing tuberculosis. For the second year there were no deaths caused by tuberculous meningitis.

TABLE 5 Cause of death in patients with tuberculosis 1952 and 1955

Cause of death	1952		1955	
	Number	Per cent	Number	Per cent
Total	35	100.0	17	100.0

Progressive or pneumonic tuberculosis	10	28.6		
Pulmonary insufficiency	5	14.3	7	41.2
Massive hemorrhage	1	2.9	2	11.7
Silicotuberculosis	2	5.7		

An evaluation of the success in treating veterans and civilian dependents is seen in table 6, which shows an appreciably higher percentage of successful results for both groups in 1955 than in 1952. The 1955 percentage of 87.6 for dependents versus 35.9 for veterans emphasizes the need for a stricter control of the Veterans Administration patient. The military tuberculosis hospital has an advantage in that the patient can be kept until his disease is inactive. However, such hospitals have a special responsibility to do everything possible to assure a low relapse

rate because military life can be conducive to the ready spread of infection

TABLE 6. Results of treatment of veterans and civilian dependents with active tuberculosis 1952 and 1955

Result	Veteran				Civilian dependent

### SUMMARY AND CONCLUSIONS

The length of hospitalization has been reduced for the military patient with tuberculosis but it is still longer than that in civilian practice

Only 50 per cent of the military patients treated for active tuberculosis are found to have a positive sputum. The majority of positive sputums convert in three months.

Dual drug therapy for a minimum of 12 months is favored. For primary treatment cases isoniazid is employed. As a companion drug para-aminosalicylic acid is probably superior to streptomycin sulfate.

Prolonged bed rest seems destined to play a minor role in the treatment program. The experience with in-hospital ambulant treatment has been very encouraging. With this trend a more aggressive in-hospital rehabilitation program is possible.

In 1954 50 per cent of the military patients treated to maximum hospital benefits had pulmonary resections. Since then this percentage has been declining with fewer segmental resections being performed for minimal residuals. This decline appears to be due to an increasing confidence in drugs, particularly isoniazid.

Temporary collapse measures have been abandoned

Treatment results of military patients are excellent because disciplinary powers result in practically all being treated to the inactive stage of the disease. Their relapse rate on follow up after three years of active duty is 3 per cent.

The program now in operation since 1951 has been successful. The serviceman contracting tuberculosis is no longer separated, pensioned for life, and his special skills lost to the Army. He is now returned to active duty, usually in less than two years, where assignments to fit his physical capabilities are provided.

# CINEPLASTY

## Results of Follow Up Study

THOMAS J CANTY *Captain, MC USN*  
EUGENE E BLECK *M. D.*

CINEPLASTY has gained in popularity in recent years but there are few follow up studies available for its evaluation. The objective of this study was to determine whether or not the cineplasty was worthwhile to the patient. If it was not effective in providing a functional artificial arm an attempt was made to discern the cause of failure.

Forty patients with known results from cineplasty comprise the basis of this report. These patients had cineplasty operations between 1946 and 1952. Of the 40 patients, 28 had biceps cineplasties and 12 had pectoral cineplasties.

### SELECTION OF PATIENTS

All of the patients were young adult males between 20 and 35 years of age. The level of amputation varied. No biceps cineplasties were done on above elbow amputations and pectoralis cineplasties were not performed on long above elbow amputations. Only the most co operative and more intelligent patients were selected. The operation was explained in detail to these patients and they were informed regarding the advantages of the cineplasty. No attempt was made to force a patient's decision.

### OPERATIVE TECHNIC

The operative technic followed was that described by various authors differing only in several minor details.<sup>1-4</sup> All of the operations were performed under general anesthesia. The skin flap raised for the muscle tunnel measured at least 3 by 3 inches and the base of the flap was made slightly wider than the sides and ends. After the biceps muscle was dissected completely from its bed the insertion was severed. The muscle tunnel was made with Mayo scissors through the thickest and most central portion of the biceps muscle and was made large enough to accommodate the index finger. It is important in biceps cine

plasty that the tunnel be made perfectly straight, with its axis directly perpendicular to the long axis of the arm

### THE PROSTHESIS

Laminated plastic sockets were used in all patients.<sup>5</sup> The muscle tunnel pegs were made of soft dental acrylic molded over a stainless steel core surrounded by a vinyl plastic tube. The pegs were either straight or "C" shaped (figs 1 and 2)

Figure 1 Cineplastic aluminum arm for shoulder disarticulation.

### TRAINING IN THE USE OF THE PROSTHESIS

This final phase of treatment is the most important aspect in ensuring a good result from the operation. It first consists of postoperative exercises of the muscle motor. Those with biceps cineplasties were taught not to supinate the forearm when contracting the biceps muscle. The training in the use of the prosthesis was conducted by the occupational therapist and the amputee instructor. In addition to dexterity with the prosthesis, functional skills such as dressing, handling a screw driver, typing, writing, et cetera, also were taught. Each patient had to pass an Achievement Test (fig 3) before he could be discharged.

11 patients were equipped with the Dorrance hook Army Prosthetics Research Laboratory (APRL) hook and APRL hand The Achievement Test was given with each of these terminal devices

Figure 2. Cineplastic arm for wrist disarticulation.

### METHOD OF EVALUATION

All patients were sent a standard questionnaire devised by the U S Army Prosthetics Research Laboratory Washington D C for the purpose of analyzing the results of cineplasty. A questionnaire study was deemed valid in reaching conclusions. This gave the patients' reactions to the procedure. In addition an objective study complete with examinations was made of patients who resided in the San Francisco Bay Area.

### RESULTS

Of the 40 patients questioned 33 (82.5 per cent) were using their prostheses. Twenty three (82.1 per cent) of these had biceps cineplasties and 10 (83.3 per cent) had pectoral cineplasties. Table 1 shows the effects of surgical complications on patients' decisions to use prostheses. Only 3 patients were

Figure 3 The Achievement Test which each patient had to pass before he could be discharged.

unable to use their prostheses because of surgical complications. Patients who were using their cineplastic prostheses gave a variety of reasons for their preference for this type over the conventional type which they had worn previously and which could be used at any time (table 2) Of the 23 patients using their biceps cineplastic prostheses, 22 preferred this type to

a conventional one, of the 10 who were using pectoral cine plastic prostheses 9 preferred them to the conventional type. Only one patient did not consider as worthwhile the extra time of hospitalization required for training in use of a cineplastic prosthesis.

Incidental	3.5		2.5
Inadequate excursion			

It should be noted that 6 patients had skin breakdown of the ineplastic tunnel, but this was not sufficient to eliminate permanently the use of the prosthesis. One patient had a contracture of the tunnel opening but was still able to use his cineplastic prosthesis.

TABLE 2 Patients' opinions as to advantages of cineplasty

Reason	Biceps	Pectoral
Arms should shrug	23	9
Arms shoulder harness	23	9
Better grip and control	22	8
Lighter and easier to use	21	7
More work in wider range	19	9
Sense of touch of normal arm	3	
Independence of arms	2	2
Permits use of velocity elbow lock		Not used

Five patients with biceps and two with pectoral cineplasties were not using their cineplastic prostheses. Table 3 summarizes the reasons these patients gave for not using their prostheses. Poor co-operation of three patients is given as a reason for failure to use their prostheses. This again points out the importance of proper selection of patients for the operation. Five

TABLE 3 *Reasons patients gave for not using cineplastic prostheses*

Reason	Biceps	Pectoral
Extra time in hospital not considered worthwhile	4	1
Like shoulder control better	3	1
Poor co-operation	1	2
Painful stump or just uncomfortable	2

Inadequate excursion		-
Does not require a prosthesis	-	-
Unsatisfactory in cold weather	-	-
Attributable to hospital management		

of the seven patients who were not using their cineplastic prostheses were wearing conventional ones, and two were not wearing any prosthesis. Table 4 shows the level of amputation in these patients.

TABLE 4 *Use of conventional rather than cineplastic prosthesis in relation to the level of amputation*

Level of amputation	Using	Not using
Below elbow	4	1
Shoulder disarticulation	1	1

Use of the cineplastic prosthesis by patients in relation to the level of amputation is shown in table 5. The figures are in conclusive, deliberate selection of patients with long below elbow stumps for biceps cineplasties produced the high per cent of good results in this group. Cineplasty is not recommended in forearm flexors and extensors because the tunnels have limited excursion and power. The use of biceps cineplasty in long above elbow stumps is not desirable because shoulder harnessing is necessary in order to hold the socket on to the stump. Pectoral cineplasties were not particularly advised on long or medium above elbow stumps inasmuch as it does not offer any great functional improvement and does not eliminate harnessing. Pectoral cineplasty for the very short above elbow

stump or shoulder disarticulation is definitely indicated, since it does make a much more functional prosthesis

TABLE 5 Use of cineplastic prosthesis in relation to the level of amputation

Level of amputation	Prosthesis

Very short	2	1	9	2
Medium	10	3	1	
Long	11	1		

### CONCLUSIONS

The good results (82.5 per cent) in patients who had cineplasties were higher than we anticipated and better than those reported by others.<sup>1</sup> In an attempt to analyze the reasons for the high per cent of good results the following factors appear to be most important

1 *The selection of patients* This cannot be emphasized too strongly, intelligent and co-operative patients who desire the operation are a great asset

2 *A modern and comfortable prosthesis* In former years the prostheses were not successfully adapted to a cineplasty and even though cineplasties were adequate surgically failures resulted from poorly constructed and poorly functioning prostheses

3 *Training in the use of the prosthesis* This is the final important phase of treatment and cannot be neglected. An occupational therapist with a fully co-ordinated program is essential

# SIMPLIFIED METHOD OF PULP CAPPING ADULT TEETH WITH CALCIUM HYDROXIDE

EVERETT D MUMAW *Captain USAF (DC)*

PHILLIP COOPER *D D S*

**T**HE TECHNICS of pulp capping, pulpotomy, and pulp curettage have developed with little benefit of basic research or scientific study. A survey of the literature indicates that there is no preferred technic of pulp capping which is generally accepted and practiced by the dental profession.

The first report of pulp capping appeared in 1756, at which time Pfaff<sup>1</sup> recommended that gold foil be placed over the exposure. In 1826 Koocher<sup>2</sup> proposed that lead lens be used after curettery with a red hot wire. Even as late as 1950, one typical textbook<sup>3</sup> recommended Pfaff's technic, but added the use of the rubber dam along with sterilization and antibiotics.

Scientific studies have justified many of the procedures used in dental practice and frequently have resulted in their improvement, however, this is not the case in regard to pulp capping. If a vital pulp is exposed in an adult patient by caries or mechanically, a common procedure is either to undertake root canal therapy or to extract the tooth. This practice is encouraged by textbooks that discourage pulp capping except in select cases, and that insist upon time consuming and almost impossible conditions of aseptic technic, temporary restorations, and use of multiple materials.

Many materials are described as acceptable, and the recommended technics of application vary widely. Among the most frequently recommended pulp capping materials are zinc oxide and eugenol,<sup>4</sup> calcium hydroxide,<sup>5-13</sup> and thymol cement.<sup>14, 15</sup> These are either used alone or are applied in combination with other materials.

The first attempts to discover a scientific basis for the use of any specific technic or material were several independent

Mumaw is now at 7030th U S Air Force Dispensary APO 12 New York N Y

studies for evaluating calcium hydroxide as a pulp capping agent. The number of cases involved in these studies varied from 6 to 45. The studies covered periods extending to 16 weeks, and presented both histologic and clinical evidence supporting the use of calcium hydroxide.

### MATERIAL AND METHOD

The present study was undertaken to obtain clinical evidence as to whether pulp capping with calcium hydroxide is a simple and effective method of treatment that can be accomplished without time consuming and complicated procedures. Whereas previous work has been largely limited to deciduous teeth, this study reports on adult teeth with no age limitation. Cases were selected at random from patients at Keesler Air Force Base, Mississippi, and Tachikawa East Air Force Base, Japan. The age of the patients varied from 17 to 46 years, averaging 27 years.

Teeth with pulp exposed by caries or by mechanical means were used and since the ultimate desired result was the same, namely preserving the vitality of as much remaining pulp as possible, pulp capping was not differentiated from pulp curettage or pulpotomy in cases where either operation was performed prior to the actual pulp capping procedure. Pulp curettage and pulpotomy were treated merely as steps to be used, if necessary, in order to remove all caries prior to proceeding with the pulp cap.

Tooth location was not considered of importance in deciding on pulp capping. Reasonable accessibility was the only criterion with posterior teeth being most frequently pulp capped. One or more of the five surfaces of the coronal portion of the tooth was involved in each of the completed restorations. The number of pulp capped teeth per patient ranged from one to three.

A few of the pulp capped teeth were used as fixed bridge and partial denture abutments. In these instances permanent restorations were made then at varying later dates the teeth were reprepared for prosthodontic abutment use.

A standard operating procedure was developed with the exception that each of the eight operators chose his own moistening agent for calcium hydroxide and used it consistently. Sterile technique was not employed either in the oral cavity or in the exposed tooth cavity nor were rubber dams, antibiotics or temporary fillings used.

Preliminary roentgenograms were taken of each tooth either before any operative work was undertaken or before the exposure was capped and only teeth that had no apical involvement and had reached full adult apical development were used in this study. In every case all caries was removed using normal clean

dental operating procedures. When the carious portion extended to the pulp, it was completely removed no matter how far into the pulp the operator had to go. If a pulp upon exposure showed any visible signs of infection, enough of it was removed to leave healthy bleeding pulp. Bleeding induced by the removal of caries was allowed to subside without interference.

The tooth cavity and mouth were then rinsed with tap water, and the cavity was air dried as completely as possible. A thick layer of calcium hydroxide powder or paste was applied directly over the exposure. The calcium hydroxide cap was lightly air dried so as not to disturb it, and completely sealed over with zinc phosphate base cement. Next, the cavity preparation was completed and a permanent restoration placed (fig. 1). Silver amalgam was the most frequently used permanent restorative

Figure 1 Pulp capping of adult tooth with calcium hydroxide

material, however, a few of the teeth in this study were restored with gold crowns, silicate cement, or acrylic filling materials. The entire procedure, including a final roentgenogram, was completed in a single appointment and the patient dismissed, to report back at specified intervals.

The size of each pulp exposure was identified by its estimated diameter, or length and breadth, in millimeters. These sizes ranged from 0.5 mm to 4.0 mm, with an average of 2.0 mm. In every case there was a clinically vital  $\sqrt{1}$  stump maiming to be capped.

The moistening agent used in mixing the calcium hydroxide pasto was tap water, sterile water anesthesia solution or zephirin chlorido. The pasto was mixed on a clean glass slab or paper pad and applied with a brush, cement instrument, amalgam carrier, or other suitable instrument.

Because of the roentgenographic characteristics of the restorative materials used, the obscuring locations, and the size of the restorations placed, most of the roentgenograms were of little use except as a check on apical conditions and periodontal membrane thickening. One operator used calcium hydroxide mixed with 25 per cent zinc oxide in an attempt to make the calcium hydroxide radiopaque. More than 25 teeth were pulp capped with this mixture, but it was found that the radiopacity of the calcium hydroxide was only slightly improved. The zinc oxide calcium hydroxide mixture gave the same clinical results as to tooth vitality as did calcium hydroxide alone.

Of the 304 teeth that were pulp capped in the course of this study, the records of 140 were not available for final analysis because of personnel movements and the exigencies of military service. Five of the remaining 164 were extracted within 2 weeks leaving 159 capped teeth that were carefully observed for a year or longer.

Each tooth was examined clinically at the end of 2, 6, and 12 weeks after being capped, if possible by the original operator. Records were consolidated by the authors and the teeth rechecked at 12 months (in 8 cases, also at 18 months). The examinations included roentgenograms, percussion, use of ice cones and vitality tests with the S S White Vitalometer or its equal. Teeth were considered to be vital if they compared in vitality with adjacent untreated teeth.

## RESULTS

The critical period for a pulp capped tooth appeared to be the first 2 weeks. Seventeen of 164 teeth caused intermittent pain, and 5 of those were extracted within the first 2 weeks. Of the other 126 had gradually become painless by the end of 6 weeks and all pain had disappeared in the remaining 6 by the end of 10 weeks. Fifteen other teeth were sensitive initially to extremes of temperature. Only one of these was still sensitive at the end of 6 weeks and it too had lost its sensitivity by the end of 12 weeks.

If pain or temperature sensitivity did not develop within 3 days it did not develop during the entire period of observation. No drugs were used to reduce either pain or sensitivity. Obviously sensitivity to extremes of temperature was not prognostic of

failure of a pulp capping operation, nor was pain necessarily so, considering that of 17 teeth which caused pain, 12 became painless within 6 to 12 weeks and were still vital at the end of a year.

The type of moistening agent used in preparing the calcium hydroxide paste did not appear to have any bearing on the clinical outcome. The number of teeth that were symptomatic after pulp capping, including the 5 that were extracted in the first 2 weeks, were evenly distributed among the various operators.

Of 164 pulp capped teeth, 5 (3.0 per cent) were extracted, but 159 (97.0 per cent) were vital and in good condition at the end of a year. The growth of secondary dentin was readily discernible in roentgenograms taken after approximately a year and a half (fig. 2). Throughout the age range of 17 to 47 years the results obtained were essentially equal.

Figure 2 Roentgenograms of lower left second bicuspid taken immediately after placing permanent restoration (left) and after 17 months (right) showing growth of secondary dentine.

Of special interest is the fact that 3 patients whose teeth have flown at altitudes of 25,000 feet are not experiencing symptoms of any kind in the area of the teeth.

### SUMMARY

In the absence of a generally accepted method and because of the complicated nature of the technique advocated, exposure of a vital pulp chamber or root canal therapy or extraction of a tooth may be saved.

A simple method of pulp capping using calcium hydroxide without use of sterile technique, rubber dam, or zinc phosphate fillings was found to be clinically effective.

Of 164 teeth that were pulp capped, 5 (3.0 per cent) became painful and were extracted, 159 (97.0 per cent) were vital and in good condition at the end of a year.

while 159 (97.0 per cent) were vital and in excellent condition after a year or more.

Twelve of the 159 teeth that were saved by pulp capping caused some pain at first, and 15 others were initially sensitive to extremes of temperature, but in all cases both pain and sensitivity had completely disappeared by the end of 12 weeks.

# SUBUNGUAL EXOSTOSIS

RICHARD S GILBERT *Lieutenant (junior grade) MSC USA*  
HERBERT H STARR *Lieutenant MC USNR*

THE PAIN and discomfort of foot disorders can have a deleterious effect on the mental attitude and physical condition of the man in service. At recruit training centers, the podiatrist sees great numbers of various foot disorders and can treat many of the more time consuming and nonsurgical conditions, thus lightening the workload of the orthopedic surgeon. Close harmony can and should exist between podiatrist and surgeon.

Subungual exostosis is only one of the many, frequently seen disorders of the toes. Exostosis occurs elsewhere in the foot, but the subungual location is important, for it is easily overlooked and causes great discomfort. Lowin<sup>1</sup> described this condition as irritative, warty overgrowth of bone occurring beneath the nails in the form of solitary, benign, slowly growing, fibrous nodules the size of peas, which almost invariably are located on the inner or tibial margin of the terminal phalanx of a great toe. They arise as a cartilaginous outgrowth and become osseous. Their attachment to the phalanx is usually complete or osseous, but may be partial or fibrocartilaginous.

Pardo Castello<sup>2</sup> stated that these lesions are not true tumors but outgrowths of normal bone tissue or calcified cartilaginous remains, varying in size from a few millimeters to two or more centimeters. Coming from the subjacent bone, they raise the whole nail or break through one of the sides or even through the plate itself, and the nail becomes distorted or is shed. Gross and associates<sup>3</sup> suggested that the condition is an inflammatory hyperplasia of bone, cancellous in character and growing upward after the osteogenic cells of the periosteum have been irritated.

The exact cause of the lesions is unknown. Most authorities agree that trauma plays an important part, if not the major factor, it certainly precipitates their growth. The possibility that subungual exostosis may represent a tetralogic anomaly has been suggested.<sup>4</sup> One theory<sup>4</sup> assumes that the growth is an attempt on the part of the terminal phalanx to form a double digit. Vinson<sup>5</sup>

From U S Naval Training Center and U S Naval Hospital San Diego Calif

stated that it is not improbable that some of these have been, in reality, supernumerary digits. Chronic infection about the nail bed is another possibility. Repeated minimal trauma over a period of years is sufficient to initiate this lesion. The great toe is the usual site, and this would appear to lend added significance to the trauma theory. It is generally agreed that the great toe is subjected to more trauma than are any of the lesser toes. Subungual exostosis is extremely rare on the hand, and most of the cases reported have involved the index finger.<sup>5</sup>

Granuloma pyogenicum, onychomycosis, ingrowing nail, fibroma subungual verruca cutaneous horn, melanoma, glomus tumor, and subungual heloma (corn) should be considered in the differential diagnosis. Roentgenographic examination is necessary to establish the diagnosis.

Very often this lesion may be present for years and remain undetected. Pain may be present, but frequently a lesion remains painless unless traumatized. The slight trauma produced by trimming the nail may be responsible for initiating symptoms. There is a tendency for the growth to increase in size, which in many cases influences the patient to seek medical advice.

The growth usually appears in patients who are from 12 to 30 years of age. A difference in incidence between the sexes is not established. The majority of those who do report a higher incidence in the female suggest that there is a relationship between the development of this lesion and the wearing of high heels.<sup>6</sup>

The treatment of choice, complete operative removal, can be accomplished by several methods depending on the location of the lesion. Special attention should be given to the nail bed and matrix during operation to prevent further nail bed deformity and to preserve the integrity of the nail matrix. With careful surgical technique the results are uniformly satisfactory.

### CASE REPORTS

**Case 1.** A 19-year-old recruit complained of pain at the mediobasal end of the right great toe. The toe became progressively more painful during recruit training and after 4 weeks of training he reported to the podiatry clinic for treatment. There was no definite history of previous trauma although the patient thought that he might have injured the toe about three years prior to his recruit training. He stated that a nodule had been present at the end of the nail for at least two years and that it had grown considerably during this period. Six months after first noticing some deformity of the toe plate he visited his family physician and was told he had a fungus infection of the nail. A proprietary drug was prescribed for daily use. No benefit was apparent after using the fungicide for three months.

Physical examination revealed a marked deformity of the nail bed and plate of the right great toe (fig 1). The nail plate was elevated and deformed. The nail-bed deformity gave the appearance of a firm, fibrous keratotic nodule breaking through and raising the nail plate at its most distal and medial part. The nail plate showed evidence of mycotic involvement.

Figure 1 (case 1) Close up of right toe illustrating the nail bed deformity

Figure 2 (case 1) (A) "Table top" exostosis as seen in roentgenogram projecting from the superior surface of the distal phalanx (B) the distal phalanx is normal in appearance

Roentgenograms revealed a large exostosis of the "table top" variety projecting upward and proximally and coming off the superior surface of the distal phalanx of the tight great toe. The exostosis was consistent with the nail bed deformity (fig 2A).

Treatment consisted of palliative measures until the completion of recruit training at which time he was admitted to the orthopedic service of this hospital for surgical removal of the growth. Figure 2B illustrates the postoperative roentgenogram.

Case 2. A 19-year old recruit complained of pain at the mediobasal aspect of the left great toe which started after one week of recruit training. The patient stated that the toenail has looked funny for the last two years. Because the toe was not painful he paid little attention to it. About eight months prior to entering the service a two-by-four piece of lumber fell on his left great toe. The toe was swollen and discolored but he did not receive medical attention. One week after the injury he lost the nail plate.

Deformity of both the nail plate and bed was seen on examination. The mediobasal portion of the nail was elevated and the lesion appeared as a firm pink nodule (fig 3A). Roentgenograms revealed a large subungual exostosis of the "table-top" variety (fig 3B).

Figure 3 (case 2) (A) The nail plate is elevated by the nail bed deformity (B) Roentgenogram demonstrates a large subungual exostosis projecting from the superior surface of the distal phalanx

Unfortunately roentgenograms were not taken at the time of initial injury. If so a more definite conclusion could be drawn as to the part trauma played in this case. Inasmuch as the patient had noticed a deformity of the nail plate before the injury the exostosis was probably already present. Whether the trauma aggravated the lesion or precipitated it is not known.

tated an increase in growth is a matter of conjecture. The exostosis was removed and the patient had no further difficulty with the toe.

**Case 3** A 40 year old nurse complained of a chronically painful left great toe. For two years she had noticed a small, pink, pealike growth just under the nail plate at the lateral distal aspect of the left great toe. There was no history of trauma, however, for three or four years she had had an ingrowing toenail. As a result of this, she developed a chronic nail infection. The pain was minimal and by wearing wide-toed shoes she remained fairly comfortable. She had never sought medical advice concerning this lesion but came to the podiatry clinic because of worry over an increase in its size.

Physical examination revealed a small, pink, pealike lesion protruding from under the lateral distal aspect of the left great toenail. The nail plate was slightly elevated in this area, otherwise it appeared normal (fig. 4). There was a considerable amount of subungual debris present. Roentgenograms revealed a small "table top" exostosis lying over and attached to the superior portion of the distal phalanx (fig. 5).

Figure 4 (case 3) The lesion protruding from under the lateral distal aspect of the left great nail plate.

Treatment consisted of surgical removal of the lesion. The specimen after operation, because of its size and shape, was considered to be a roentgenogram.

Figure 5 (case 3) (A) Roentgenogram shows exostosis projecting from distal phalanx of left great toe (B) Lesion removed at operation illustrating the discrepancy between actual size of lesion and size of visible portion seen on the roentgenogram.

### SUMMARY AND CONCLUSIONS

Subungual exostosis usually occurs on the great toe. Although the cause has not been fully established, trauma definitely plays an important part. Pain may be severe, mild, or absent. Growth of this lesion may be progressive and often causes the patient to seek medical attention. Such bone growth may exist in any case of nail bed and nail plate deformity and emphasizes the importance of roentgenographic examination. A lateral view plain film demonstrates the growth.

In differential diagnosis, subungual exostosis is confused most frequently with onychomycosis, which often is associated with the exostosis as described in one of the case reports.

Complete operative removal of the exostosis, with care not to injure the nail bed or matrix, is the treatment of choice and consistently produces satisfactory results.

# SIMPLIFIED MICRORADIOGRAPHY OF BONE AND TEETH

JOHN T. ISTOCK, *Chief Hospital Corpsman USN*  
CLARENCE W. MILLER  
FRED L. LOSKE, *Captain DC USA*

**A** TECHNIC has been developed for the microradiographic study of mineralized tissues using relatively inexpensive radiographic equipment. This technic makes the procedure available to the laboratory, hospital, or teaching institution with a limited research budget. The advantages of investigating biological structures with roentgenologic microscopy were reviewed by Engström, Bellman, and Engfeldt.<sup>1</sup>

Our method is a simplified version of the techniques described by Lamarque,<sup>2</sup> Engström,<sup>3</sup> Arprino and Engström,<sup>4</sup> Engfeldt and Zetterstrom,<sup>5</sup> and Vincent,<sup>6</sup> and as such may serve to entice more investigators into this field of study. The techniques described by the above investigators require the use of relatively expensive beryllium window roentgen ray tubes, and generally, vacuum type systems, whereas our technic employs the cheaper nickel window tube, and omits use of a vacuum system.

The unit we use is a grenz ray (soft roentgen ray) generator manufactured by the Ullman Corporation (fig. 1). This is a small, compact unit, adaptable for use in limited spaces. It consists of a self rectified generator with current range of 0.5 ma and voltage range of 0.30 kvp, plus a tube with tungsten target. Inherent filtration is 0.0008 inch of nickel. The unit is designed for continuous operation, and the heat produced by long exposures has little effect on the microradiograph. It has been noted that if a brief cooling period is allowed between exposures, the current output is more stable. Extra stabilizers can be employed to regulate the incoming current if a continuous fluctuation is noted. This usually is caused by intermittent loads on the power line.

Fresh or fixed bones or teeth are cleansed of soft tissue and cut into sections 50 to 100 microns in thickness (fig. 2) on the Scott and Crisp Tooth Sectioner.\* Sections selected for micro-

From Naval Medical Research Institute National Naval Medical Center Bethesda Md.  
David Scott and Laurence Crisp National Institute of Dental Research Bethesda Md.

radiography are hand lapped to a final thickness of approximately 30 microns. When the desired thickness has been obtained the specimens are washed in absolute ethyl alcohol and dried for one hour. Satisfactory results are obtained with sections varying between 30 and 100 microns. Sections thinner than 30 microns have been used, but unless a specially designed supporting holder is employed, distortion and poor detail result. Distortion always occurs when the specimen is not in uniform contact with the emulsion of the film.

Figure 1 Soft roentgen ray apparatus used for microradiography

With the availability of many fine grain, high resolution spectroscopic plates such as Eastman Kodak 548 and 649 (500 to 1 000 lines per mm), fine detail can be obtained. The GH<sup>100</sup> type emulsion is used instead of the lower sensitivity O type emulsion.

Figure 4 Microradiograph of cross section of human femoral cortical bone from a normal 37 year old male. The varying mineral distribution is readily seen when osteons are compared. The interstitial bone in general appears as more mineralized; the lacunae of the osteocytes appear as black spots. A large Volkmann's canal is entering from the endosteal side into a poorly mineralized osteon. Other Volkmann's canals are visible ( $\times 150$ ).

Figure 5 Microradiograph of six week old anorganic bone implant. Donor bone (A) shows the quantitative distribution of mineral salts in the various osteons. Cortical defect (B) is filled with mineralized callus and anorganic bone chips (C) ( $\times 32$ ).

0.125 inches of lead, then placed in the roentgen ray beam 4 cm from the target. This short distance was selected in order to decrease exposure time. The low milliamperage output of the small roentgen ray generator used prohibits longer target-film distance. A longer target-film distance would be preferable, but with proper centering of the specimen, good results are obtained with the shorter distance.

The average exposure technique for samples of mineralized bone ground to 30 microns, is 12 kvp and 4.5 ma for 35 minutes. For specimens thicker than 30 microns, an increase in kilovoltage and exposure time is required. The exposure time may be increased to as much as 60 minutes for bone sections of 75 microns in thickness. An exposure of 50 minutes at 20 kvp and 2.5 ma produces satisfactory results with tooth sections of 100 microns in thickness.

Spectroscopic plates are processed in Eastman Kodak D 19 developer for 7 minutes at 68° F, with slight agitation each minute during development. The plate is then rinsed in alcohol for 30 seconds with continuous agitation, washed in running water and placed in a standard acid fixer for 30 minutes. After washing for 30 minutes in running water, processing is completed by drying the film in a dust-free atmosphere. If a brown stain appears on the plate, most of it can be removed after the plate has been processed and washed by bathing the plate for 3 to 5 minutes in 95 per cent ethyl alcohol.

The finished radiograph is covered with a standard coverglass and examined under a microscope. Standard photomicrographic techniques are used for recording fields of interest. Photomicrographs ranging from 50 to 250 diameter magnification can be obtained.

Figure 4 shows the uneven distribution of the mineral salts in normal human femoral bone. The Haversian systems (osteons) differ among themselves as well as from the surrounding tissue in degree of mineralization. The organic nature of the osteocyte and its capsule are relatively transparent to roentgen rays and thus appear as round or oval dark spots.

In their study of heterologous bone grafting, Hurley and Losee<sup>10</sup> took microradiographs of bone sectioned through the implant site at various periods after operation. Figures 5 and 6 show the mineral bonding between anorganic donor bone chips and host bone in a six weeks postoperative specimen and leave no doubt as to the biological acceptance of the graft material.

Figure 7, a longitudinal section of human cortical femoral bone, illustrates the complexity of the systems of Haversian and Volkmann's canals, which must be considered in evaluating

Figure 4 Microradiograph of cross section of human femoral cortical bone from a normal 37 year-old male. The varying mineral distribution is readily seen when osteons are compared. The interstitial bone in general appears as more mineralized; the lacunae of the osteocytes appear as black spots. A large Volkmann's canal is entering from the endosteal side into a poorly mineralized osteon. Other Volkmann's canals are visible ( $\times 150$ )

Figure 5 Microradiograph of six week old anorganic bone implant. Donor bone (A) shows the quantitative distribution of mineral salts in the various osteons. Cortical defect (B) is filled with mineralized callus and anorganic bone chips (C) ( $\times 32$ )

Figure 6 Higher power microradiograph of implanted anorganic bone chips. Mineral bonding is apparent between donor chip (A) and host callus (B). Multiple black dotted areas are lacunae which permit easy passage of roentgen rays ( $\times 200$ )

Figure 7 Microradiograph of a longitudinal section from same human cortical bone used in figure 4. Complexity of the canalicular system of cortical bone is apparent. Volkmann's canals are quite numerous and do not appear to have a uniform pattern ( $\times 100$ )

microradiographs. On the enamel side of the dentino-enamel junction near the tip of the dentinal cusp, the spindles become visible because of their organic composition. A region of lower mineral content is represented by the increased radiolucency. In figure 8 the hypocalcified tufts or whorls are seen as wavy black bands in the inner enamel running at right angles to the dentino enamel junction.

Figure 8 Enamel spindles (S) and dense organic matrix area are visible at the tip of the dentinal cusp (D) in the enamel (E)

## Clinicopathologic Conference

Valley Forge Army Hospital Phoenixville Pa \*

### RECURRENT COMA

**Summary of Clinical History** A 20-year old white man was admitted to this hospital in a semicomatose state. No medical history was immediately available. His friends indicated that he had been out the night before but had not been drinking heavily. On the morning of admission he had gone to work but had not felt well. Later in the day he had returned to his room to rest and at about 1400 hours had been found by friends holding his head as if in pain and mumbling incoherently. During the next day he gradually became more rational, and a medical history was obtained except for the events of the preceding two days, for which the patient had a complete amnesia. Past medical history was noncontributory. During the preceding year he had become interested in hypnotism and had practiced it with his friends. He had been known to make bizarre statements concerning previous existences for example he claimed to have existed in Rome in the year 1 B. C. as a sewer rat.

**Physical Examination** On admission, the patient was stuporous and responded sluggishly. Pulse was 44/min and irregular, temperature 98°F, blood pressure, 110/80 mm Hg, and respirations 12/min. No evidence of trauma was found. The pupils were round and regular and reacted to light. A pigmented chorioretinitis was seen bilaterally. Neurologic examination was negative.

---

Brig Gen Sam F Seeley MC, USA Commanding General From the Pathology Service  
Capt Dale M Schulz MC, USAR Chief

**Laboratory Studies** An electrocardiogram showed sinus bradycardia and sinus arrhythmia. Roentgenograms of the chest and skull were negative. Laboratory findings on admission were within normal limits. Tests for barbiturates and bromides were negative. There was a faint positive reaction for salicylate in the urine specimen. Blood alcohol was below the level of significance.

**Course in Hospital** A spinal puncture revealed an initial pressure of 290 mm of water. Queckenstedt's test was not done. The patient was restless and had to be restrained during the procedure. He responded to painful stimuli but did not become lucid until the day after admission. On the third hospital day he had a mild recurrence of symptoms. He continued to complain of headaches and was transferred to the neuropsychiatric department. A repeat lumbar puncture showed an initial pressure of 600 mm of water. The spinal fluid was clear with 12 cells (2 polymorphonuclear leukocytes and 10 lymphocytes), total protein, 22 mg/100 ml, and sugar, 54 mg/100 ml.

The patient complained of difficulty in focusing his eyes and stated that his headaches had begun with a recent fainting spell. He was not vomiting and did not complain of nausea. On the ninth hospital day he again became comatose, and neurologic examination again failed to reveal any abnormality. During the next week he continued to improve, although his gait was still unsteady. Another lumbar puncture, done while the patient was sedated with Amytal Sodium (brand of amobarbital sodium) showed an initial pressure of 160 mm of water. On the 22d hospital day he was found dead in the bathroom.

## DISCUSSION

**Doctor Bealer** From the data given in the protocol it would seem that the symptoms must represent increased intracranial pressure and the question is to determine the exact cause. The symptoms on admission and those present throughout the hospital course are of a general nature: i.e. confusion, amnesia, headache, syncope, and coma. As an aid in localizing the lesion, only the ataxia, visual blurring, irregular bradycardia, and slow respiratory rate may be of significance and it must be remembered that these may also only represent generalized increased pressure.

In arriving at a tentative diagnosis it might be well first to rule out some of the common causes of such a clinical picture in males in this age group. The first thing that comes to mind is the possibility of trauma and a subacute or chronic subdural hematoma. The history is obviously open to much question and such an injury could well have been sustained; however, the normal roentgenograms of the skull, the absence of signs of trauma, the absence of blood in the spinal

fluid and the normal neurologic findings with no signs of meningeal irritation make this an unlikely diagnosis. Second one might think of some infectious process but opposed to this possibility are the normal spinal fluid, normal routine laboratory findings (in particular the leukocyte and differential counts) the afebrile course and the absence of any foci of infection such as the middle ear sinus or lung. Third I think that the findings of the toxicologic studies plus the routine laboratory work make unlikely such entities as diabetes renal disease drug intoxication et ceteta.

I believe that the two most likely possibilities are brain tumor and hemorrhage the latter probably from an aneurysm. In support of the diagnosis of neoplasm certainly all of the signs of generalized increased intracranial pressure present here would be expected. An increase in the cerebrospinal fluid protein is common as are increased cell counts particularly the mononuclear cells but this does not always occur. The most common single sign in such cases is papilledema which was absent throughout this patient's course. However papilledema is not seen in about 15 per cent of cases particularly if the tumor is of such proximity to the optic foramina as to occlude them. One would expect signs of early optic nerve atrophy however if such were the case. If one were to speculate on the location of the neoplasm the two most striking findings would be the bradycardia with irregularity and the slow respirations. On this basis one might assume the lesion to be in the medulla near the nuclei of the vagus. A very small lesion so critically located might easily account for the relatively short clinical course. Also the possibility of hemorrhage within such a tumor or transient edema might well explain the intermittent nature of the illness.

My second diagnostic choice—hemorrhage probably from an aneurysm—seems unlikely for reasons similar to those given for a subdural hematoma—the normal neurologic findings and absence of signs of meningeal irritation the afebrile course normal spinal fluid, and normal leukocyte count. Also signs of cranial nerve involvement are often present in such instances especially if the aneurysm is in the circle of Willis. An elevated blood pressure might be expected especially if the hemorrhage were sudden and if one postulates that each of the episodes over the 22-day clinical course was due to further hemorrhage. One might expect to see blood pressure changes at these times. Also a chronic subdural hematoma from the rupture of a venous channel between the arachnoid and dura mater must be thought of. It would be possible in such a case to have a normal cerebrospinal fluid with fluctuating signs and symptoms. Papilledema may in such instances be absent.

Doctor Davenport. In essence we have the case of a young man with a negative past medical history who was admitted in coma. The

night before admission he had been drinking, but not excessively. On the morning of admission he awakened stated that he did not feel well but went on duty. During the morning he complained of feeling worse and went to his barracks to lie down where a short time later he was found semicomatose mumbling incoherently and holding his head as if in pain.

The diagnosis of cerebral vascular accident and specifically hemorrhage immediately comes to mind. We must think of primary subarachnoid and subdural hemorrhage. Subarachnoid hemorrhage in the vast majority of instances is due to rupture of an aneurysm. Most aneurysms are of the congenital or "Berry" type but a few are syphilitic, arteriosclerotic or mycotic in origin. At autopsy about 8 per cent of a large series of patients with cerebrovascular accidents will have a primary subarachnoid hemorrhage. Such series show that this lesion appears to have its greatest incidence between the ages of 40 and 50 years. Premonitory symptoms are rare but weeks or months before rupture occurs there may be paralysis of one or more of the cranial nerves due to pressure of the aneurysm. Focal signs are not noteworthy and if they occur are related to the site of the hemorrhage. Generalized symptoms such as headache, vomiting, convulsions and coma are common. Coma as a presenting symptom occurs in 30 per cent of cases. Vomiting occurs in about 50 per cent and headache in almost 100 per cent. With a large hemorrhage the temperature is usually elevated, the pulse rate increased and the rate and depth of respiration altered. The blood pressure is usually elevated. Pupillary findings such as loss of accommodation to light and inequality in size are very common. Stiffness of the neck occurs uniformly. The cerebrospinal fluid is bloody in all patients with primary subarachnoid hemorrhage.

In subdural hemorrhage a history of injury or the presence of contusions or lacerations of the scalp indicative of head injury is important. A period following injury in which the patient is relatively free of symptoms and then lapses into coma is very important in the differential diagnosis. A bloody spinal fluid under increased pressure may occur with either subdural or subarachnoid hemorrhage as may focal neurologic signs, headache, coma and alterations in pulse, respiration and blood pressure. The patient under consideration could from his history have suffered either a subarachnoid or subdural hemorrhage. The diagnosis however could not be substantiated as there were no neurologic signs at admission, the spinal fluid was not bloody and no evidence of cerebral injury could be found by either physical or roentgenographic examination. I do not believe that the history of the patient's interest in hypnotism or the bizarre statements which he had allegedly made are of any significance.

Doctor Hamilton: The striking thing about this patient is the intermittency of his symptoms. However there is no question that these

symptoms were manifestations of increased intracranial pressure. Subdural hematoma, subarachnoid hemorrhage or tumor are all capable of producing increased pressure. In view of nonbloody spinal fluid, the first two possibilities seem unlikely. Therefore an intracranial neoplasm would seemingly be the only other logical explanation for the clinical picture presented in the protocol.

In view of the absence of neurologic signs, it is impossible to precisely localize such a tumor. However, the history of recurrent bouts of coma, headache and syncope suggests two possible sites, namely the third or fourth ventricles.

Tumors of the third ventricle may lie entirely within it, producing few symptoms and signs other than those of increased intracranial pressure. Characteristically, these manifestations differ from those produced by tumors elsewhere by being intermittent. Patients with such lesions may suffer from severe headaches which appear suddenly and which apparently are often precipitated by putting the head in a certain position. At times such pain can be relieved by sudden nodding. These attacks are secondary to a transient hydrocephalus produced by a "ball valve" action of the tumor which suddenly obstructs the flow of cerebrospinal fluid. The blockage is relieved by movement of the head. Such episodes may be so severe that sudden coma and even death may occur.

Tumors of the fourth ventricle, on the other hand, produce increased intracranial pressure early by obstructing the ventricle and seldom give rise to other symptoms until late. Symptoms when present are not marked and may be in the form of unsteadiness of gait or tremor. Frequently, it is impossible to differentiate between a lesion in the fourth ventricle and one in the midline of the cerebellum.

On the basis of the characteristics of tumors located in either the third or fourth ventricle, I am inclined to make as my primary diagnosis an intrinsic neoplasm, possibly a colloid cyst of the third ventricle. I believe that death was probably the result of an acute recurrence of blockage.

Doctor Lucas, from the initial findings and history, one could have postulated that the patient's condition was due to trauma or to some toxic factor such as alcoholism or an overdose of drugs. The subsequent course and findings, such as the initial spinal fluid pressure of 290 mm of water with a second lumbar puncture of 600 mm of water, are suggestive of some cerebellar abnormality. I believe that the third spinal fluid pressure of 160 mm of water cannot be interpreted accurately inasmuch as Amytal Sodium is known to lower the spinal fluid pressure.

When one correlates the patient's apparently worsening state during hospitalization with the increased spinal fluid pressure and the history

of unsteady gait, the question of a tumor of the posterior fossa should be considered. I am unable to account for the cause of the bilateral choriorretinitis and can see no connection between this and such a tumor.

One other comment is that I do not see the necessity for having done repeated spinal taps. With an increased pressure and an associated space-occupying lesion there is the possibility of herniation of the cerebellar tonsils.

Doctor Davenport: Doctor Felton, do you have a comment?

Doctor Felton: I have no other diagnoses to offer and would agree with those suggested, in the order given. The absence of history or evidence of trauma, of localizing neurologic signs, and of signs of toxicity suggests that there was no condition such as subdural or extradural hemorrhage or cerebral abscess.

The protocol up to the last sentence does not particularly indicate that other diagnostic procedures might have been of help. The fact that the patient died suddenly, when associated with the previous findings, points to the intracranial location of his obviously organic disease. In view of this, the findings of carotid arteriograms or pneumoencephalograms would probably have been of considerable help diagnostically. It is doubtful, however, if there was sufficient clinical indication to recommend these studies at the time.

Doctor Van Hoorn: In view of the intermittent character of the symptoms of this patient, which must have originated in the brain or brain stem, it seems possible to me that there had been recurrent bleeding in a tumor. This tumor could be a glioma.

Dr. Sealer's diagnoses:

Neoplasm, possibly in medulla, or ruptured cerebral aneurysm.

Dr. Hamilton's diagnosis:

Neoplasm of third ventricle, possibly colloid cyst.

Dr. Lucas' diagnosis:

Neoplasm of posterior fossa.

#### PATHOLOGIC FINDINGS

Doctor Schulz: The significant pathologic findings were confined to the central nervous system. The brain weighed 1400 grams and the convolutions were widened with narrowing of the sulci. The brain was closely applied to the dura with little or no subarachnoid fluid visible over the vertex. There was no cerebellar pressure cone. The most striking feature grossly was the ballooning of the third ventricle to form a thin-walled cyst 3 cm in diameter. A needle inserted into

the right lateral ventricle withdrew 100 ml of clear cerebrospinal fluid with resulting collapse of the bulging third ventricle

A midline sagittal section made in the fresh state showed slight dilatation of the anterior portion of the aqueduct of Sylvius with occlusion at the level of the inferior colliculus. The lining of the dilated portion of the aqueduct was ragged and slightly injected. After fixation a 2 mm spherical mass could be recognized in the subependymal region of the mesencephalon protruding into and partially obliterating the aqueduct (fig 1). Multiple cross sections of the brain showed none are

Figure 1 Section of mesencephalon showing the spherical tumor in the subependymal region that protrudes into the aqueduct

dilatation of the lateral ventricles, extreme dilatation of the third ventricle, and no abnormalities of the fourth ventricle. The ependymal linings were smooth and glistening.

Microscopically, the tumor was composed of intertwining bundles of fibrillary processes with relatively few nuclei. The cells were distributed irregularly (fig 2) with no evidence of anaplasia and only rare mitotic figures. Sections taken from 1 to 2 mm anterior to the main tumor showed dilated aqueduct with the ependyma interrupted by tufts of proliferating astrocytes and fibrillary processes (fig 3).

This neoplasm belongs to the group described by Boykin and associates<sup>1</sup> as subependymal glomerate astrocytomas. Because of the

Figure 2 Photomicrograph of the subependymal glomerate astrocytoma

Figure 3 Section of aqueduct showing interruption of the ependyma by tufts of proliferating astrocytes and fibrillary processes

strategic location neoplasms of this type in the aqueduct are probably the smallest that can cause death

#### Pathologic diagnoses

- 1 Astrocytoma (2 mm) of mesencephalon with obstruction of aqueduct of Sylvius
- 2 Dilatation of anterior portion of aqueduct, moderate
- 3 Dilatation of third ventricle extreme of lateral ventricles moderate

#### MANAGEMENT OF INTRACRANIAL BLEEDING

The general practitioner and specialist may be called for advice after the catastrophic collapse of an apparently healthy individual. The sudden onset of profound neurological signs and symptoms in such a patient always suggests intracranial hemorrhage. All patients suspected of having intracranial bleeding should be subjected to prompt cerebral angiography to determine the pathological nature of the lesion. In analyzing 100 cases of this type with cerebral angiography a definite vascular malformation was demonstrated in 69 percent. A positive diagnosis as to cause or associated manifestation was made in 85 percent of the cases. While there are certain inherent risks in angiography no additional complications appear to have been introduced into the treatment of intracranial bleeding by having performed the procedure even as early as two hours after the presumed onset of the bleeding. Such risks as may exist seem minor in comparison with the existing risk of the lesion itself. In cases of ruptured aneurysm of the circle of Willis the survival rate following neurosurgical intervention is 75 percent. In a smaller but comparable group those treated by conservative means had a survival rate of 18 percent. Indicated for intracranial bleeding conservative therapy for intracranial bleeding is actually the

## MENTAL ILLNESS AND CLASSIFIED INFORMATION

MORTIMER V KLEINMANN Jr *Major MC USA*

EDWARD F KRISE, *Captain MSC USA*

THE medical profession and the public are both becoming more sophisticated in their attitude toward mental illness. Almost everyone knows that half of our nation's hospital beds are occupied by the mentally ill. Slow progress is being made toward improving our institutions and there is some evidence that the various legislative bodies are taking cognizance of the problem. However, when a psychiatric disturbance occurs close to home, in the family, in the organization or in someone we know, it is still regarded with fear and sometimes panic.

Nowhere is this more severe than when it occurs in a civilian or military person who has had access to classified material. It is immediately assumed that our entire security is at stake and that local or national secrets are about to be spread abroad for the perusal of enemy agents.

When evaluating a person as a security risk from the psychological standpoint, we are concerned with whether or not an illness or personality deviation exists which impairs his ability or judgment with regard to classified information. Executive Order 10450 states that "an adjudication of insanity, or treatment for a serious mental or neurological disorder without satisfactory evidence of cure" disqualifies a person from receiving a security clearance. Special Regulation 380.160.2 adds the following factors as raising a presumption of a security risk: "conviction for or manifested tendencies of homosexuality, conviction of felonies indicating habitual criminal tendencies, addiction to the use of alcohol or drugs habitually and to excess, without adequate evidence of rehabilitation."

While these orders spell out certain requirements, it usually evolves upon the local physician to determine whether or not these requirements are being met. Such phrases as "serious," "evidence of cure," and "rehabilitation" require considerable individual evaluation and interpretation. Let us consider some

of the more common forms of mental illness from the standpoint of their being security risks

### NEUROSIS

In considering the attributes of neurotic people in general, we do not believe that the presence of a neurosis automatically presupposes the existence of a security risk. We know that the neuroses are internal problems. They are conflicts existing within the individual between his impulses (usually unconscious) and his ability to control them. He may be anxious, he may be hypochondriacal, or he may be compulsive, but he is not disoriented and his conflict is not between himself and the environment. Even in the phobias where the individual responds with inappropriate fears to some situation in the environment we know that these stimuli are symbolic of some unconscious and internal conflict.

Usually the neurotic is a worrier. He expends a great deal of his psychic energy in introspection. Generally, his circle of friends is small because he does not generate the warmth and outgoingness that encourages interpersonal contacts. Frequently he is a very conscientious worker transferring much of his concern and compulsiveness to his job. This is not to say that every neurotic individual should be cleared for every job. On the contrary, there may be many reasons why a neurotic should be denied a clearance. His stress threshold may be low. His hypochondriacal tendencies may cause him to lose much time from important work and his various phobias may definitely limit his flexibility in a particular assignment. On the other hand he may have many skills to offer. In such cases a careful evaluation of the individual in terms of his job would seem indicated.

One might carry the argument further, to a theoretical plane which is beyond the scope of this paper and arrive at the conclusion that in some cases certain types and degrees of neuroses actually reduce the likelihood of an individual's being a security risk. In any event the authors have never seen a case in which the presence of a neurosis resulted in a breach of security.

### PSYCHOSES

The psychoses are an entirely different matter with regard to protecting classified information. When a psychotic condition is found to exist in a patient, the assumption is made that the individual is not responsible for his actions and therefore should not have access to classified material. This assumption is not universally true inasmuch as many a law abiding schizophrenic is earning his living and rearing his family unobtrusively or at times, bearing only the label "eccentric." In general however, one cannot predict the course of a psy

chosis with sufficient accuracy to justify granting a security clearance

Despite the foregoing, an actual breach of security due to the existence of a psychosis is a rarity. In the functional psychoses the patient frequently tends to become markedly withdrawn and isolates himself from other people. Exceptions to this are the manic and certain phases of the paranoid and catatonic schizophrenias. Because it is sometimes difficult to determine the exact type of psychosis which exists early in the disease process, one is never justified in taking chances once the condition is detected. Primarily the psychotic individual (manic, depressed, or schizophrenic) represents a severe actual or potential danger to himself, to those around him, and of course to the military mission of his unit. Because most of these conditions become clinically apparent slowly, forecasting themselves with eccentric behavior, it is usually possible to take the necessary protective measures before serious damage is done.

### TOXIC REACTIONS

The toxic reactions present another picture. They are frequently sudden in onset and may be due to the administration or withdrawal of drugs, the imprudent use or withdrawal of alcohol, some febrile illness such as pneumonia, or more commonly some combination of the foregoing. The patient suffering from a toxic reaction is usually delirious and may babble incoherently. In our experience the combination of pneumonia and withdrawal from alcohol in a person habituated to its excessive use has constituted the most common security embarrassment. It is not necessary to postulate the improbable condition of an enemy agent being present during such an episode to meet the requirements for a breach of security. The dissemination of classified information, even in delirious fragments, to people who have not been properly cleared and briefed, regardless of their loyalty is to be avoided whenever possible.

### CHARACTER AND BEHAVIOR DISORDERS

This group, which includes personality disorders, sexual deviations, and immaturity reactions, represents the most common threat to local and national security. Most of these people look normal and appear to behave in a normal manner most of the time. Many of their deviations from the normal are handled at the unit level without ever coming to the attention of the security officer or the physician. Frequent AWOL's, excessive indebtedness, and more than an occasional brush with the local police may be indicative of an emotional limitation which makes the individual a poor security risk. Less detectable and, therefore, more dangerous, are the tavern braggart, the immature

security guard who must impress his girl friend with his importance and the near deviate who habituates disreputable sections of town "just for kicks." The undetected homosexual is regarded as a risk not so much from the danger of his being blackmailed although this exists but because of the rapidity with which he may make strong emotional attachments to persons of short acquaintance.

Most people live double lives within themselves, satisfying their aggressive needs and frustrated desires through phantasy and sublimation. The people in the character and behavior disorder group tend to act out their impulses much as the child does when he plays cops and robbers or fancies himself as the current western hero. The blend of phantasy and reality can be so subtle that the individual may be hard pressed to separate them resulting in remarkably poor judgment as to what is possible and what is not or what is safe and what is unsafe. This frequently results in a legal controversy over whether or not these people are responsible for their actions. It is generally believed that they are, but each case must be judged on its merits. The important thing is that people in this group are usually not detected until after they have been assigned sensitive jobs and may have already compromised the security of their unit.

#### EARLY TREATMENT

The physician who first sees a mentally disturbed person who has had access to classified material is called upon to answer several important questions. What condition does the patient have? How serious is it? How long may it be expected to last? Does it constitute a security risk and if so what special precautions are indicated? Most important is the decision as to how the case is to be handled from the very beginning.

**Neuroses.** The patient who is suffering from a neurosis will frequently present himself voluntarily to the physician with his emotional problem or after adequate evaluation of the patient's organic complaints the physician may decide that the problem lies in the emotional sphere. Very often the patient has already suspected this or accepts it after brief token resistance during which he says, "But surely my emotional problems couldn't cause my chest pain" or "But doctor this pain is real. I'm not imagining it." The doctor's genuine acceptance of the pain as real and his firmly expressed opinion that emotional disturbances can cause the patient's symptoms may be all that is necessary to orient the patient toward the cause of his illness. Certainly some patients will reject this concept completely and insist that an organic cause must be found. The physician who allows himself to be duped into performing numerous physical examinations and repeated laboratory pro-

ceduros only serves to reinforce the patient's opinion that he, indeed, has some physical illness

In those cases where the patient recognizes that he has an emotional problem and is ready to talk about it, another difficulty arises. The patient's security clearance may be higher than that of the physician. The therapist must then inform the patient that this situation exists and insist that nothing of a classified nature be brought up. This problem is more apparent than real since in most people the difficulty has existed for some time and rarely relates to a specific job. This is particularly true when the job is highly specialized and the patient is an expert in his field. It is less applicable when the job is routine and the patient relatively untrained as in the case of a security guard whose job "gets on my nerves." Usually the largest portion of the difficulty will be found to lie in the realm of interpersonal relationships between the patient and people who have had an important influence on his personal life such as parents, siblings, wife, et cetera.

The physician who has not had psychiatric training will certainly not wish to embark upon a course of long term psychotherapy. His prime motive is to ameliorate the patient's distress sufficiently to allow him to remain at his job. Frequently this may be accomplished by merely affording the patient the opportunity of discussing his problems in confidence with someone whom he knows is not going to reveal what is said during the interview. Very often confused issues are clarified remarkably when the patient is required to put into words what had once been vague concepts and unexpressed and diffusely felt hostilities. Through all this the doctor plays the role of a listener. He does not enter into an active critique of the patient's thoughts or activities. He certainly does not play God and offer specific advice about such things as marriage, divorce, or change of jobs or career fields. These are decisions the patient must make for himself when he has attained a better understanding of the factors involved.

Even if the therapist admits that a plan proposed by the patient appears to be reasonably sound, in the event of failure this may come home to roost as a direct accusation that the plan was specifically suggested and encouraged by the doctor. Principally the doctor just listens and may occasionally point out the apparent existence of mixed feelings which seem to be contributing to the patient's difficulties. This is not psychoanalysis. It does not deal with basic unconscious drives or the Oedipus complex. This listening type of therapy is designed solely to allow the patient to express his feelings accurately so that they become clearer to him and thus easier to deal with.

Not all cases are amenable to this type of therapy and the physician must particularly avoid any dramatic techniques in which he attempts in one or two interviews to reveal to the patient the "deep, underlying, unconscious" cause of his neurosis. Usually he will fail to impress the patient at all but occasionally he may uncover material which he is not competent to handle and do serious harm to his patient. In any case where the physician feels that the patient's illness seriously interferes with the performance of his duties or the physician doubts his own ability to handle the situation he has no other course but to recommend transfer to a general hospital with neuropsychiatric facilities. As long as the patient is well oriented and responsible for his actions no special security measures are indicated beyond notifying the security control officer of the patient's admission to the hospital and proposed transfer so that de briefing can take place and a replacement obtained if necessary.

**Psychoses.** The psychotic patient presents a simplified but sometimes urgent problem. As long as he is in a psychotic state and not responsible for his actions he must be regarded as a security hazard. He must be isolated and attendants provided. The security officer should be notified so that appropriate steps can be taken to protect confidential material or information for which the patient was responsible such as codes, safe combinations, keys and passes to restricted areas et cetera. It is also necessary to brief attendants regarding their responsibilities toward any classified information to which they may be exposed.

Within a short time after admitting the patient the physician will be required to express an opinion as to the severity of the illness, the likelihood of the patient returning to duty in a short time, a long time, or never, and finally as to whether the current illness represents a security hazard in regard to future assignments. The question of arranging an emergency transfer of the patient to a general hospital will also arise and may seem to require an urgent decision.

The answers to these questions will be determined for the most part by (1) the clinical state of the patient and (2) the physician's diagnosis. It is possible that the doctor's own anxieties about mental illness and the bizarre forms in which these conditions present themselves may lead him to attempt a rapid diagnosis and disposition of the case. A reasonably thorough physical examination and a good history taken from the patient, his relatives, associates, and superiors will do much to reduce the confusion and assist in charting a course. The desire of the physician is to help the patient and in the cases we are discussing to protect security as much as possible. Rapid transfer of these patients may not do this and indeed

may only serve to increase the security hazard by exposing the patient to numerous other people with inadequate clearance

An early, but tentative, decision should be made concerning whether the patient's mental aberration represents a primary psychiatric process such as schizophrenia or a manic depressive psychosis or whether it is secondary to some other condition of an infectious, toxic, or cardiovascular nature, et cetera. If the patient belongs to the latter group, treatment directed at the basic illness will usually alleviate the psychiatric symptomatology to the extent that the patient need not be evacuated as a psychiatric case and may not require evacuation at all. Most toxic reactions are of short duration and subside as the fever comes down, the basic infection is brought under control, or a reasonably normal physiologic balance is restored. Every city hospital and almost every physician has a favorite "cocktail" which is administered to the patient suffering from delirium tremens or alcoholic hallucinosis. These have largely been replaced by the ataractics which are reasonably safe and rapid in action. By using their sedative effect the physician allows himself time to evaluate his patient more critically and is in a better position to decide on the necessity of a transfer.

In the case of the alcoholic, where the doctor cannot give reasonable assurance that the condition will not be repeated, it may be necessary to transfer the patient to another post. However, the ends of security may be better served if the patient is given a less sensitive job within the original organization, provided he is able to perform other tasks satisfactorily.

In the case of the functional psychoses, particularly the schizophrenias, ultimate transfer to a general hospital should be planned. Admittedly, the physician in the station hospital or outlying medical installation is faced with a real problem when he attempts to provide care for a psychotic patient without closed ward facilities. The absence of an adequate restraint section and trained closed ward personnel may seem to present an overwhelming problem, the only answer to which is heavy sedation of the patient and immediate transfer out of the area.

Here again, the need for haste may be more apparent than real. Although the psychotic is considered to be mentally incompetent, large areas of his personality frequently remain intact. This is particularly true in the early stages of the illness at the time when the doctor in the station hospital is most likely to see the patient. A kindly, accepting, and professional attitude may do much to calm an anxious and hostile patient and may make the difference between a patient who can be handled routinely and one who throws the area into a turmoil and taxes the abilities of all concerned.

Not all cases are amenable to this type of therapy and the physician must particularly avoid any dramatic techniques in which he attempts in one or two interviews to reveal to the patient the "deep, underlying, unconscious" cause of his neurosis. Usually he will fail to impress the patient at all but occasionally he may uncover material which he is not competent to handle and do serious harm to his patient. In any case where the physician feels that the patient's illness seriously interferes with the performance of his duties or the physician doubts his own ability to handle the situation he has no other course but to recommend transfer to a general hospital with neuropsychiatric facilities. As long as the patient is well oriented and responsible for his actions no special security measures are indicated beyond notifying the security control officer of the patient's admission to the hospital and proposed transfer so that debriefing can take place and a replacement obtained if necessary.

**Psychoses** The psychotic patient presents a simplified but sometimes urgent problem. As long as he is in a psychotic state and not responsible for his actions he must be regarded as a security hazard. He must be isolated and attendants provided. The security officer should be notified so that appropriate steps can be taken to protect confidential material or information for which the patient was responsible such as codes, safe combinations, keys and passes to restricted areas, et cetera. It is also necessary to brief attendants regarding their responsibilities toward any classified information to which they may be exposed.

Within a short time after admitting the patient the physician will be required to express an opinion as to the severity of the illness, the likelihood of the patient returning to duty in a short time, a long time, or never, and finally as to whether the current illness represents a security hazard in regard to future assignments. The question of arranging an emergency transfer of the patient to a general hospital will also arise and may seem to require an urgent decision.

The answers to these questions will be determined for the most part by (1) the clinical state of the patient, and (2) the physician's diagnosis. It is possible that the doctor's own anxieties about mental illness and the bizarre forms in which these conditions present themselves may lead him to attempt a rapid diagnosis and disposition of the case. A reasonably thorough physical examination and a good history taken from the patient, his relatives, associates, and superiors will do much to reduce the confusion and assist in charting a course. The desire of the physician is to help the patient, and, in the cases we are discussing, to protect security as much as possible. Rapid transfer of these patients may not do this and indeed

advance of the patient's arrival. Alerting the security officer at the general hospital to which the patient is being transferred helps to reduce the possibility of a security break after the patient has lost the control of his own medical unit.

The handling of the psychotic patient at the local installation may be summed up as follows:

1. Attempt to bring the acute phase under control prior to transfer.

2. Work closely with the local security officer with particular regard to the selection and briefing of attendants and the protection of any classified information or material to which the patient may have had access.

3. Alert the receiving installation as to the situation both through medical and security control channels.

**Character and Behavior Disorder Group** The role of the medical service in the handling of personnel with character and behavior disorders would appear to be rather poorly defined. Administrative methods of disposition recommended by boards convened under the provisions of AR 635 208<sup>1</sup> and AR 635 209<sup>2</sup> frequently bypass medical channels, and if the physician is asked to see these cases it is usually only for the purpose of ruling out any condition which might warrant the individual's appearance before a medical board. By the time the doctor is consulted, the subject may have been involved in sensitive work for many months or even years. The man's commanding officer has had to wait until the individual's transgressions or inaptitude has not only become readily apparent through repeated actions but has also resisted the required attempts at rehabilitation.

In routine military assignments the above procedure has demonstrated its value, but where security information is involved it may not be feasible to wait so long. Early detection of those persons who represent potential security hazards because of personality patterns can be facilitated by a little extra effort on the part of the local physician. The commanding officer of any unit charged with a sensitive military mission is certainly going to be receptive to any reasonable procedure or policy which enhances his security control. The doctor, through contact with unit commanders, should encourage the early referral of those servicemen and civilians who show evidence of poor personality traits such as immaturity, frequent AWOL's, apparent inability to handle routine personal problems, excessive indebtedness, and difficulty with the local police.

In many cases a recommendation for will not be indicated, but a transfer to a less

Not infrequently the patient has suspected that something was wrong for some time and although frightened and suspicious, is anxious for help and will move in a positive and co-operative manner toward the physician who offers protection and assistance. For this reason the use of subterfuge should be scorned. A straightforward and honest approach is indicated. Within the limits of his ability to comprehend, the patient should be advised as to what is being done for him. In answer to his questions concerning his isolation and the presence of attendants, he can be told frankly that the doctor believes that he is emotionally upset at the present time and that this arrangement is considered necessary.

To the uninitiated it might seem that this would be just the thing to set the patient off on a wild attempt to escape. Experience indicates the contrary. Since the patient is extremely sensitive to all that is going on about him he will be quick to sense an honest approach and although he may disagree with the doctor's opinion he will feel better able to cope with what he considers to be an honest error rather than something he thinks is a plot to incarcerate him.

Sedatives may be necessary and should be selected and used with due regard to the physical condition of the patient. Barbiturates particularly amobarbital sodium given intravenously, can be used to calm the very hyperactive patient, but the physician should not be surprised to discover that even an anesthetic dose has only a short effect. Of the newer drugs, promazine hydrochloride given in adequate dosage is the author's choice. Large doses are to be avoided in the hypertensive or cardiac patient. In the otherwise healthy patient the drug is generally considered to be quite safe and the rapid administration of the necessary dosage may be attempted. We start with 100 mg of promazine given orally or 50 mg intramuscularly every two hours until the desired effect is obtained. Between doses the patient is watched carefully for signs of excessive drowsiness or a precipitous fall in blood pressure. Clinical improvement is frequently obtained with the first dose. If the patient shows no untoward response to the drug initially the dosage schedule may be accelerated as necessary. When it has been established that the patient tolerates the drug well, intramuscular administration of higher doses can be used when a very rapid or more pronounced effect is desired.

Once the acute phase has been brought under control the physician may begin making realistic plans for the transfer of his patient. The degree of security information involved may well determine the place to which the patient is transferred and the method of transportation. The receiving installation should certainly be advised of the situation well in

advance of the patient's arrival. Alerting the security officer at the general hospital to which the patient is being transferred helps to reduce the possibility of a security break after the patient has left the control of his own medical unit.

The handling of the psychotic patient at the local installation may be summed up as follows:

1. Attempt to bring the acute phase under control prior to transfer.

2. Work closely with the local security officer with particular regard to the selection and briefing of attendants and the protection of any classified information or material to which the patient may have had access.

3. Alert the receiving installation as to the situation both through medical and security control channels.

**Character and Behavior Disorder Group.** The role of the medical service in the handling of personnel with character and behavior disorders would appear to be rather poorly defined. Administrative methods of disposition recommended by boards convened under the provisions of AR 635 208<sup>1</sup> and AR 635 209<sup>2</sup> frequently bypass medical channels, and if the physician is asked to see these cases it is usually only for the purpose of ruling out any condition which might warrant the individual's appearance before a medical board. By the time the doctor is consulted, the subject may have been involved in sensitive work for many months or even years. The man's commanding officer has had to wait until the individual's transgressions or inaptitude has not only become readily apparent through repeated actions but has also resisted the required attempts at rehabilitation.

In routine military assignments the above procedure has demonstrated its value, but where security information is involved it may not be feasible to wait so long. Early detection of those persons who represent potential security hazards because of personality patterns can be facilitated by a little extra effort on the part of the local physician. The commanding officer of any unit charged with a sensitive military mission is certainly going to be receptive to any reasonable procedure or policy which enhances his security control. The doctor, through contact with unit commanders, should encourage the early referral of those servicemen and civilians who show evidence of poor personality traits such as immaturity, frequent AWOL's, apparent inability to handle routine personal problems, excessive indebtedness, and difficulty with the local police.

In many cases a recommendation for administrative discharge will not be indicated, but a transfer to a less sensitive position

within the unit or even to another area may be in order. The screening of all incoming personnel would put an excessive burden on the doctor and is not practical, but the selective interviewing of those individuals whose previous performance suggests that they may fall into the groups we are discussing will undoubtedly increase the integrity of the unit with regard to protecting classified information. It is certainly consistent with the responsibility of the physician that he work closely with his commanding officer and the security officer in the protection of his unit through the early detection and elimination of those people who represent actual or potential security risks.

### SUMMARY

Mental illness represents a threat to national security and often poses a difficult problem in medical management.

The presence of a *neurosis* does not presuppose the existence of a security risk. Only through careful evaluation of the manifestations of the illness in relation to the demands of the job can the existence of a security threat be determined.

Because the course of a *psychosis* cannot be predicted with accuracy, psychotic patients should be relieved of their security clearance even though an actual break of security due to the existence of a psychosis is, in our experience a rarity.

Persons suffering from *character and behavior disorders* represent the most common threat to national security when placed in sensitive positions. The early identification and effective administrative management of such patients through the close co-operation of physician unit commander, and security officers can reduce the hazards associated with these disorders.

We have emphasized the importance of early treatment, the danger of rapid and poorly planned evacuation, and the necessity for integration of the skill of the physician and the function of the security officer. Basic psychological and medical techniques that may be employed by the physician who is faced with the problem of mental illness in patients who have access to classified information have been suggested.

# FLIGHT INDOCTRINATION PROGRAM

At a United States Marine Corps Air Station

RUSSELL G WITWER *Captain MC USN*

**T**WO years ago a new program of aviation selection was instituted at this activity in an attempt to lower the high attrition rate of U S Marine Corps aviation candidates in the Naval Air Training Command. There are many variables that enter into attrition rates, but the results achieved to date must be considered most favorably.

Under the old regime, various categories of flight applicants were ordered to the U S Naval Air Station, Pensacola, Fla., from all sections of the United States, upon successful completion of their flight aptitude tests and flight physical examinations. At present, the majority of Marine Corps aviation candidates, Regular or Reserve, are processed at this air station prior to receiving orders for flight training. Those of officers and men are obtained from several sources which include:

1 Unrestricted commissioned officers who have successfully completed, or are in attendance at, a Basic Course at the Marine Corps Schools, Quantico, Va., at the time of application.

2 "Platoon Leaders Class (Aviation)" program consisting of college students who receive two six week periods of training prior to their senior year of college during two summer vacations from college. Those who desire flight training are administered flight physical examinations, flight aptitude tests, and further indoctrination as outlined in this article during the second six week training period. After graduation from college and when commissioned, they are ordered to report to this air station in order that their physical qualifications may be reaffirmed.

3 Aviation officer candidates, who are recent college graduates and who receive at Marine Corps Schools, Quantico, a 10 week training course leading to a commission, followed by assignment to flight training.

4 Enlisted personnel selected for assignment to flight training who are assigned to the Marine Corps Schools.

---

From U S Marine Corps Air Station Quantico Va

Candidates from any of these sources who fail to qualify are immediately returned to their nonaviation duties without undue loss of time or money. Those who do qualify are ordered to Pensacola for training as student naval aviators for a period of about 18 months.

A complete flight physical examination including refraction, is given to all applicants, even though they have been previously qualified. During the 24 months covered by this report 41 such candidates were rejected for physical defects. Causative factors in most instances have been (1) the lengthy interval between time of original examination and reporting here, (2) hasty examinations, possibly due to the pressure of recruiting programs, and (3) previous passing of some applicants following eye exercises\* from civilian sources.

The U S Navy Aviation Selection Tests<sup>1</sup> are given to those candidates not having previously passed them provided that an interval of at least one year has elapsed since a previous failure as well as to those who have never given the tests. These written examinations take about three and one half hours to complete and are preceded by a brief explanatory talk by a flight surgeon. They consist of

1 Aviation Qualification Test, which is primarily a test of general intelligence

2 Flight Aptitude Rating Battery (FAP), which is divided into three different written tests: (a) The Mechanical Comprehension Test which deals with the ability of the individual to perceive physical relationships and handle familiar concepts of everyday mechanics rather than technical matter found in textbooks. This test has been found to be most useful in predicting success in the flight training program. (b) Spatial Apperception Test designed to measure ability to visualize the relationship between the attitude of a plane and the territory over which it flies. (c) Biographical Inventory, an untimed questionnaire containing elements of personal history, expressions of interests and attitudes and selected informational items that have been found to differentiate between passing and failure groups. Those receiving passing grades in the Selection Tests are then scheduled for a flight physical examination at the rate of 20 a day until each group is completed.

Upon final approval by the Bureau of Medicine and Surgery, those found to be physically qualified and aeronautically adapted for duty involving flying are scheduled to receive four indoctrination flights each of one hour duration in the T 34 training aircraft. The purpose of this flying is to minimize attrition of Marine officer students at Pensacola. It does so in two ways. First, it lets the applicant experience the sensations and problems of single engine aircraft flying thereby shaping his own

decision—"You like it." Second, it provides the Marine Corps Schools Flight Interview Board with more basis for its recommendations concerning the applicant's suitability—"It likes you."

Flights are preceded by a briefing on emergency and cockpit procedures, and include rudiments of ground operations and fundamental flight maneuvers. Applicants follow through on controls. Aerobations or abrupt maneuvers are forbidden. The pilot reviews each flight with the applicant, then writes up the applicant's reaction to what he has experienced.

The fourth and final step is the meeting with the Flight Interview Board which is chiefly concerned with the determination of the motivation of the applicants for flight training. It indicates by endorsement, on each application, its recommendation in this regard to the Commandant, U S Marine Corps. It is noted that the academic and leadership performance of those applicants in, or graduates of the Basic Course, Marine Corps Schools, are considered by the Board as a direct reflection of his motivation.

From February 1955 through February 1957, a total of 1,733 flight applicants were examined by this medical department. Of these, 904 (52.16 per cent) were found to be physically qualified and received passing grades in their Flight Aptitude Tests. (Over 1,100 flight physical examinations having no connection with this program were also conducted during the two-year period.)

Of the 904 candidates accepted medically, 41 (4.53 per cent) voluntarily withdrew prior to their first flight and 63 (6.96 per cent) voluntarily withdrew following one or more flights. Of the remaining 800 applicants, 101 (11.37 per cent) were rejected by the Flight Interview Board. Of the physically qualified candidates, 684 (75.66 per cent) completed indoctrination flights and were finally accepted by the Flight Interview Board. The slight difference in final totals can be explained by the fact that a few candidates were either not recommended for commission, were hospitalized for illness or injury, or were subsequently rejected by the Bureau of Medicine and Surgery.

Most frequent reasons given by those who dropped at their own request were (a) loss of interest, (b) family opposition, (c) decision not to extend their period of active duty, and (d) the extensive time element required for flight training.

#### CONCLUSIONS

Testimony has been given to Congress by the services' witnesses, as far back as 1955, that the cost of flight training is estimated to be about \$120,000. Informal estimates from the Flight Training Command indicate that the direct cost of pro-

dueing a naval aviator is approaching \$115 000 A total of 220 candidates either withdrew voluntarily or were rejected by the Flight Interview Board 41 additional applicants who had previously passed their flight physical examinations were rejected by the Quantico medical department

Assuming that all 261 candidates not qualified would have been eliminated during the early stage of their flight training, a great monetary saving to the Government would be represented. It is quite conceivable that some of the candidates would advance to later stages of training at even greater cost. In addition, much reduction in lost time waste of manpower, and inconvenience to all concerned is represented. As previously stated those who fail during any one of the four stages of this indoctrination program are immediately returned to their original place of duty.

The U S Marine Corps recruiting program also has apparently been assisted by the enthusiasm of the members of the Platoon Leaders Class following their brief experience with aviation. The best judges are the procurement officers in the field, and they contend that they are helped immeasurably by the interest created not only among those given the flights but also in the number of friends influenced by the candidates.

The final attrition rates for the years 1955 and 1956, based upon 16 to 18 months of training have not been completed. In summary we can only quote the following excerpts from a special Report issued by the U S Naval School of Aviation Medicine.

"Differences in the over all attrition rates are actually reflections of the difference in the DOR (dropped on request) rate among various groups. Although there are few variations in rates between groups for other types of attrition none of these variations is significant. The significant differences among the groups are for voluntary withdrawals only.

\*Another figure which stands out is the relatively low Marine Corps officer DOR rate since they were at one time a high DOR group in comparison with other Ols (officer under instruction). Apparently their screening and flight indoctrination program has paid off in reduced attrition."

We are of the opinion that the Marine Corps attrition rate will be even lower when the final results of the past two years flight training have been ascertained. This low rate is a result of more rigid adherence to flight physical examination standards giving candidates an opportunity to actually experience basic flying and careful screening prior to assignment to flight training.

## WHAT PRICE PEACE OF MIND?

"It is a rapidly moving world we live in growing more and more complex year by year. Great social changes are going on. The improvements in communication have exposed each of us to many new stimuli. If we cannot react to them satisfactorily they call forth in us anxiety and hostility. An increasing number of people cannot enjoy being quiet and undisturbed and alone.

"In order to adapt successfully to this new world one must take thought. One must know one's self. One must contemplate with some objectivity his relationships with other persons and learn to understand his own reactions. Many will need the help of psychiatrists to accomplish this.

"If we take the easy way and merely "tranquilize" our patients with new or old drugs we may seduce them into a bogus health but it will weaken their adaptive capacities. Our patients will lose some of the keenness needed to live in this accelerated world there may be more traffic accidents and the cult of relaxation may degrade our morale. If we psychiatrists surrender to this easy kind of therapy and give up the careful study of our patient's problems we might as well let the manufacturers of the "tranquilizers" contract with the municipalities to put tons of drugs into the reservoirs of drinking water. Then everybody will relax.

"No psychiatrist would subscribe to such a ridiculous notion. Our aim is to make patients responsible and at peace with themselves. For those patients capable of adaptation there are no cheap wholesale shortcuts. Lasting peace of mind can be bought only dearly, by self knowledge."

## CASE REPORTS

### Larval Granulomatosis

Diagnosis by Needle Biopsy of the Liver

OGDEN C. BRUTON Colonel MC USA  
WILLIAM J. JAFFURS Captain, MC USA

**L**ARVAL GRANULOMATOSIS (visceral larva migrans) as a clinical entity causing extreme degrees of eosinophilia associated with visceral granulomatosis in children ingesting polluted soil is well documented. The dog and cat ascarides have been thought to be the main offenders, however other larval forms not accustomed to the human host in their normal life cycle have also been identified. The diagnosis of the condition may be strongly suspected from routine clinical data, however the diagnosis can only be made by finding the larvae in body tissues. Usually the liver has been the tissue studied ante mortem, although the brain, lung, heart and other organs have harbored the larvae in post-mortem specimens. Liver tissue has been obtained for such study during abdominal exploration. It has been stated that the diagnosis will be infrequently made "as long as laparotomy is the only means of specific diagnosis." The ease with which liver needle biopsy in children may be done has been pointed out, and its use in suspected larval granulomatosis is demonstrated by the following case report.

#### CASE REPORT

A two year-old boy was admitted to the hospital with fever, cough, general malaise and enlargement of the abdomen of one month duration (fig. 1). There were four siblings three to eight years of age in good health. The mother had allergic rhinitis. The father was overseas and in good health. When the mother delayed coming to the hospital a home visit revealed the family to live in a rural filth. Several dogs of various ages were owned by neighbors although the boy's family had no pets. The patient was said to spend much of his playtime picking dirt from between the cracks in a paved walkway and eating it.

The patient had pneumonia six months prior to admission which lasted a month and appeared to respond completely with the use of antibiotics.

From Tripler U S Army Hospital APO 438 San Francisco Calif and Walter Reed Army Hospital Washington D C

**Physical Examination** On admission the patient appeared both acutely and chronically ill, with a prominent abdomen caused by an enlarged spleen and liver, which were 6 and 5 cm below the costal margin. The nasal mucous membranes were wet and swollen and appeared to be of the allergic type. The tonsils were large and hyperemic with exudate on both. There were coarse rales and rhonchi throughout both lung fields. The fundi were normal.

*Figure 1 The abdominal enlargement is obvious in this photograph of the patient. The liver and spleen have been outlined on the abdomen.*

**Laboratory Findings.** The white blood cell count was 48,000 per  $\mu$ l with a differential count of 13 per cent neutrophils, 21 per cent lymphocytes, 65 per cent eosinophils and 1 per cent basophils. Hemoglobin was 8.7 grams per 100 ml. Bleeding time, coagulation time, platelet count, urinalysis and blood culture were normal or negative. The total serum bilirubin was 0.4 mg per 100 ml. cephalin-cholesterol flocculation, negative, thymol turbidity, 9 units, alkaline phosphatase, 9.2 Bodansky units and total blood protein 10.2 grams per 100 ml were

albumin 2.7 grams giving an albumin-globulin ratio of 0.4. Electrophoretic analysis of the blood serum proteins gave a total of 9.48 grams per 100 ml with 4.5 per cent albumin, alpha globulin 3.5 per cent, alpha<sub>2</sub> 8.3 per cent, beta 9.8 per cent, and gamma globulin 33.8 per cent. Stool specimens contained no blood, ova, or parasites. Skin tests for tuberculosis, histoplasmosis, coccidioidomycosis, and blastomycosis were negative. A study of the bone marrow was interpreted as showing hyperplasia with marked increase in the number of eosinophils and eosinophilic precursors.

**Course in Hospital.** On penicillin and streptomycin therapy the patient's acute respiratory signs and symptoms subsided rapidly. The clinical impression was that this child represented a rather typical example of granulomatosis caused by visceral larva migrans. Accordingly, one week after admission when his acute respiratory infection had subsided a liver needle biopsy was performed. The biopsy specimen revealed multiple granulomas (fig 2) in various stages of develop-

Figure 2 Granulomas in the liver biopsy specimen. (X 125)

ment apparently localized in the vicinity of the vascular channels. A few larvae of *Toxocara canis* lying within granulomas were found after many sections were searched (fig 3). Because of the obstructive

Identified by Dr. Paul C. Beaver, Prof. of Parasitology, Tulane University School of Medicine.

nature of the tonsils he had an uneventful tonsillectomy and adenoidectomy before his discharge one month after admission. There was no change in his white blood cell count or eosinophilia, and his spleen and liver remained enlarged. No specific treatment was attempted. Measures to prevent more infection were strongly advised at the time of discharge.

Figure 3 *Toxocara canis* larva in liver ( $\times 450$ )

**Subsequent Course** Follow up investigation one year after study found the family still living in circumstances conducive to continued infection. The patient's liver was 2 cm below the costal margin and the spleen 3 to 4 cm. A roentgenogram of his chest was reported as normal. His white blood cell count was 18,200 per  $\mu$ l with a differential count of 22 per cent neutrophils, 33 per cent lymphocytes, and 45 per cent eosinophils. The hemoglobin was 10.8 grams per 100 ml.

#### DISCUSSION

That certain parasites are unable to continue their life cycle in a foreign host and spend their life meandering through various tissues is a fascinating story. However, it becomes disturbing when one suspects the probable widespread casual infection in man, with or without clinical manifestations. That this high

degree of casual infection does exist is supported by studies revealing a majority of cats and young dogs harboring parasites<sup>1</sup> and the almost universal close association of man with these animals with little thought of prevention of infection. In a 10-month period, June 1955-March 1956, 61 of 169 (36 per cent) dog stool specimens examined at the Hawaiian Medical Laboratory, without regard to age or clinical condition of the dog, were found positive for some intestinal parasite.<sup>2</sup>

It seems entirely probable that some unexplained neurologic disorders in children are caused by these infections. It has not been determined with certainty that mild infections in nonallergic individuals produce the typical clinical picture as in the case reported. Certainly in the past larval granulomatosis has not always been differentiated from familial eosinophilia, eosinophilic leukemia, Loeffler's syndrome, retinoblastoma and endophthalmitis. The finding of an eosinophilia greater than 20 per cent and a history of eating dirt should suggest the diagnosis. Other symptoms relative to the respiratory tract, central nervous system and an enlarged liver and spleen further support the diagnosis. A liver biopsy showing granulomas along with the clinical picture would appear to furnish a presumptive diagnosis, although the specific etiologic diagnosis can only be made by identification of the larva. The small size of the parasite and the few sections usually made from a biopsy specimen make the finding of the parasite unlikely. Complete sectioning of the specimen in a heavy infection, as in the reported case, increases the likelihood of identification.

#### SUMMARY

A two-year-old boy with a history of eating dirt was found to have an enlarged liver and spleen, white blood cell count of 48,000 per  $\mu$ l (65 per cent of which were eosinophils) and a total serum protein of 9.48 grams per 100 ml (33.8 per cent of which was gamma globulin). A liver needle biopsy revealed many granulomas and several larvae identified as *Toxocara canis*. It is believed that liver needle biopsy is a safe method of proving the diagnosis of larval granulomatosis.

of Isuprel 1:200 solution, in 5 ml of Alevaire nebulized with compressed air under a positive inspiratory pressure around 18 cm H<sub>2</sub>O. Expiration was allowed to take place passively. Prior to the start of this treatment he appeared his usual self, exhibiting the usual labored breathing but with no suggestion of critical respiratory impairment. He seemed composed and free of any manifest anxiety or apprehension.

After 4 to 5 minutes of treatment a critical change in his status was obvious. He became severely dyspneic, experienced a sensation of suffocation and had to withdraw from the face mask. He appeared cyanotic. A wild, frightened apprehensive expression was evident. There was no complaint of chest or precordial pain. He was coherent. He remarked that the treatment was not helping him as it usually did. After a pause of a minute or two he appeared to improve, so the face mask was replaced and the procedure was continued. After a period of 1 to 2 minutes he removed the face mask again because of increasing dyspnea. His anterior thorax was now markedly elevated and appeared to be "trapped" in an advanced inspiratory position. He was deeply cyanotic and gasped desperately for air. His face was again distorted by a wild, frightened stare. His respirations were shallow with evident use of the accessory muscles. His lips were pursed during expiration. The radial pulse rate was 160, weak and difficult to elicit. His blood pressure was 110/60 mm Hg (one hour later on the ward blood pressure had risen to 160/90). The cervical veins were greatly distended in the sitting position. Heart sounds were distant. Cardiac rhythm was regular. Abundant moist rales and expiratory wheezes were heard throughout both lung fields. He had 3+ pedal edema. The liver was easily palpable below the costal margin.

The patient was taken to the ward where the following measures were instituted: oxygen by tent, extremity tourniquets, aminophylline intravenously, Dicumarol (brand of bishydroxycoumarin), mercurial diuretics, and increased amounts of digitalis. Over the next several hours he improved rapidly. Since that time he has been maintained on low sodium diet, mercurial diuretics as required, digoxin 0.5 mg daily, expectorants, and pneumodilators.

#### DISCUSSION

The explosive onset of this complication had to be explained by a pathophysiologic process capable of producing an abrupt alteration in ventilatory and/or cardiocirculatory function. The diagnoses considered were (1) acute cardiac arrhythmia, (2) acute myocardial infarction, (3) acute massive pulmonary embolism, or (4) acute alterations in respiratory pressure dynamics adversely affecting ventilation and circulation. Cardiac arrhythmia and myocardial infarction were ruled out by appropriate clinical observations and electrocardiograms. The diagnosis of massive pulmonary embolism was not too satisfactory because

of the absence of many major criteria (1) complete absence of any type chest pain, (2) no acute electrocardiographic changes, (3) no roentgenographic changes compatible with pulmonary infarction or acute pneumonitis, (4) absence of hemoptysis (5) absence of a febrile episode, (6) absence of pleural effusion (7) absence of overt phlebitis (8) absence of jaundice, and (9) absence of shock or collapse

Previous studies have proved that pulmonary embolism may occur without infarction,<sup>1-4</sup> but I believe that an embolus of almost any size at that time would have produced infarction. The patient's long standing obstructive emphysema, cor pulmonale, and hypertensive cardiovascular disease, provided abnormal pulmonary circulation and congestion, which are ideal prerequisites for infarction following embolism. The work of Chapman and associates<sup>1</sup> supports this point. In addition there are theoretical considerations relative to circulatory dynamics under IPPB which argue against the assumption proposed by some that this form of mechanical respiration by increasing velocity of circulation, would stimulate release of embolic showers from already established venous thrombi factories. The fact that clinical and laboratory findings in pulmonary embolism may be extremely varied or nonspecific is appreciated by the author through personal experience and a review of pertinent literature.<sup>1-4</sup> However, when a diagnosis lacks the support of many major criteria as listed above, a curiosity persists about other possibilities.

problem gradually produced, in logical sequence, an association of ideas and facts heretofore scattered and unrelated

Once the mechanisms were organized into a logical sequence of events, the end result was analyzed in terms of three variables that were present simultaneously so as to provide vector forces acting in additive fashion to give an explosive resultant. The three variables believed to be responsible for the patient's complication on IPPB are

- 1 The presence of severe obstructive pulmonary emphysema
- 2 The use of positive inspiratory pressure alone, at a high level (18 cm H<sub>2</sub>O), allowing a passive expiratory phase
- 3 The presence of marked cardiorespiratory abnormality manifested by cor pulmonale and hypertensive cardiovascular disease requiring appropriate therapy

#### SEVERE OBSTRUCTIVE PULMONARY EMPHYSEMA

In normal breathing, the respiratory muscles change the shape of the thorax. As the thorax is actively expanded, an increasingly negative interpleural pressure is produced. An associated reduction of pressure in the alveolar space occurs, producing a pressure gradient (transpulmonary pressure) in the tracheobronchial tree. In the presence of unobstructed air channels, air flow proceeds almost to completion during the inspiratory phase of the cycle.<sup>17,18</sup> This allows air flow into the lungs until alveolar pressure approaches atmosphere pressure, or peak mask pressure in IPPB. Because the alveolar ventilation volume will parallel pressure change, the approximation of mask and alveolar pressure will assure that the alveoli do not change shape more than volume. Expiration then proceeds to completion, the exhaled volume equals the inhaled volume, and respiratory pressure dynamics remain normal.

In the presence of airway obstruction, resistance to air flow prevents the alveolar spaces from filling to mask pressure,<sup>17,18</sup> and the normal sequence of events is altered by the slowing of air flow. The respiratory muscles effect a change in the shape of the thorax, thereby producing an increasingly negative interpleural pressure. The negative interpleural pressure in turn reduces the pressure in the alveoli. This latter situation causes a change in shape of the alveoli that is in the nature of a ballooning or distention. Because the resistance to air flow prevents the alveolar pressure from  
10  
pressure, the volume ventilating  
change in shape. With the stimulus  
sufficiently inflating the airway, volume

as was the case in this patient. This greatly aggravates the sequences outlined above, whereby an increasingly negative interpleural pressure and alveolar distention are produced.

Because the emphysematous patient is further handicapped by altered elastic properties of the lung and thorax, a vicious cycle of disproportion between alveolar distension and alveolar emptying is established. The consequences of this are as follows:

1 Expiration does not proceed to completion, the volume of air exhaled is not equal to the volume inhaled, and air trapping results.

2 Inspiration starts from a progressively higher point on the lung volume scale (hyperinflation) with each respiration.

3 A process of increasing functional residual volume takes place resulting in further impaired alveolar ventilation and hypoxia. As a consequence of the latter, increased capillary permeability ensues.

4 In addition, an increasingly negative interpleural pressure occurs, providing a "suction like" action on the pulmonary capillaries. This results in increased capillary permeability conducive to edema formation.

Now, to account for the explosive nature of this complication one must understand how the above outlined sequence of events was intensely aggravated by voluntary hyperventilation. High level positive pressure inflating of the airway, in the presence of significant bronchiolar obstruction, can provide a stimulus invoking a stress response (hyperventilation) similar to that noted in emphysematous patients performing a maximum breathing capacity. Not infrequently we have to caution and instruct patients about overbreathing during IPPB. In patients with obstructive emphysema, a gross change in thoracic configuration with fixation at a high inspiratory level has been noted. This adverse process of overdistention will continue until either the obstruction is relieved or sufficient elastic recoil presents in the overstretched lungs to expel in the time available an amount equal to the inspired volume.

The importance of a prolonged expiratory phase in patients with emphysema as it relates to the production of positive pressure against the pulmonary capillary, has been stressed by Barach and associates.<sup>4</sup> The prolonged expiration of the patient with bronchospasm results in an increased positive pressure between the site of bronchial constriction and alveolar capillary. However, an acutely elevated negative pressure is introduced within the chest; there is an abrupt termination of

expiratory effort and a consequent loss of the backward pressure on the pulmonary capillaries. As this occurs, the pulmonary capillaries become immediately more permeable. These authors also reviewed the dynamics involved in the production of pulmonary edema following induced tracheal stenosis. Their experiment illustrates how increases in the negative intrapleural pressure, by exerting a suction action on the pulmonary capillaries, increases pulmonary capillary permeability, congestion, and edema formation. This latter condition affects the relationships between the forces of hydrostatic pressure, osmotic pressure, and tissue turgor which operate to maintain the homeostasis of capillary permeability.

Paine and co workers<sup>20</sup> have demonstrated that abnormal fluid exchange in the lung tissue may result from disturbances of hydrostatic and osmotic pressure relationships as described by Starling;<sup>21</sup> they conclude that Starling's principles apply to the pulmonary as well as to the systemic circulations, and must be considered in all future studies relating to the pathogenesis of pulmonary edema.

In applying this basic information to the problem, a sequence of mechanisms was established which explained the occurrence of edema. Let me re-emphasize that this adverse effect of creating a high negative intrathoracic pressure while inflating the airway under positive pressure relates specifically to the presence of an obstructed air flow. In the presence of an unobstructed airway, and normal forces of elasticity and compliance of the lung and thorax, this complication would not be expected. Let us now consider the second variable which added to the dilemma as an additive vector force in the production of the resultant.

#### HIGH LEVEL POSITIVE INSPIRATORY PRESSURE ALLOWING A PASSIVE EXPIRATORY PHASE

In speaking of mechanical respiration, the type used must be specified. In particular, it is not enough to speak only of "positive pressure" treatment of pulmonary edema. The type used may be of paramount importance to result and ventilatory and cardio-circulatory dynamics in the individual patient. The question as to which is the best mechanical method of artificial respiration is still unsettled. Much of the confusion has resulted from the practice of evaluating methods and machines on persons in a normal physiologic state rather than on patients in circulatory and/or respiratory failure. A basic classification of mechanical respiration includes three types<sup>22,23</sup>

1 Intermittent positive pressure. Administered as positive, inspiratory pressure, allowing expiration to occur passively or

to be carried out against positive pressure. Through acquired use, however, IPPB has become identified with the singular use of positive inspiratory pressure.

2 Alternating positive negative pressure in cyclic fashion during inspiration and expiration respectively

3 Continuous positive pressure throughout both phases of the respiratory cycle

In this patient a high level of pressure (18 cm H<sub>2</sub>O) was used. Expiration was allowed to occur passively. In the presence of the severe bronchospasm present at the time, we may assume that the adverse effect of increasing negative intrathoracic pressure resulted. This appeared to be manifested clinically in the patient's thoracic position of advanced inspiration, indicating air trapping. If a negative or positive pressure expiratory phase had been provided, this complication might have been prevented.

It is now readily apparent that the first two variables are related. The one was important only through the simultaneous presence of the other.

#### IPPB IN THE PRESENCE OF CARDIOCIRCULATORY AND/OR RESPIRATORY ABNORMALITY

Numerous studies have been conducted evaluating the use of positive intermittent pressure. In normal persons no significant adverse physiologic changes in cardiopulmonary dynamics have been recorded. This has been documented using all available varieties of machines and pressure alterations.<sup>14</sup> The production of adverse physiologic effects with positive pressure inflation of airways was regularly noted in patients suffering from respiratory and/or circulatory failure. The results in this latter group were in distinct contrast to those in normal persons. The following adverse effects, especially when pressure is in excess of 8 cm H<sub>2</sub>O was applied, were recorded:

1 A fall in systemic blood pressure

2 A decrease in cardiac output. This reaches levels of 41.9 per cent in some severely disabled patients.

3 Increased systemic venous pressure. This reached levels of 70 per cent in patients in failure.

4 Prolongation of circulation time

5 Reduction in blood volume

6 Elevation of cerebrospinal fluid pressure

Studies by Maloney and co-workers<sup>14</sup> suggested a good correlation between the circulatory effects and the mean mask pressure.

They demonstrated that these adverse effects were regularly eliminated by machines employing a negative phase during expiration. Introducing a negative expiratory phase avoided the circulatory depression, improved systemic blood flow, and permitted patients to maintain blood pressure and cardiac output at normal levels.

Our patient was unquestionably in very poor respiratory and cardiocirculatory status. This was well established in his protracted history of pulmonary emphysema, cor pulmonale, and hypertensive cardiovascular disease. It may have been that progressive deterioration of his cardiocirculatory status was the most important variable of those discussed, even though by itself (without high level IPPB) it could not have produced the explosive emergency which occurred.

By integrating these facts we can understand how the simultaneous presence of certain mechanisms, acting in the manner of additive vector forces, produced an alteration in function. The resultant explosive formation of pulmonary edema represented a summation of many forces. This took place even though by standard classification the treatment method was indicated for the disease state. The lessons or recommendations that might be drawn from this experience are:

- 1 Mechanical respiration is an excellent therapeutic tool but demands an understanding of methods, machines, and physiologic effects in treating respiratory and/or cardiocirculatory problems.

- 2 It is especially important to find out whether the air channels are obstructed or unobstructed, and whether the cardiocirculatory status is normal or to some degree abnormal.

- 3 Positive pressure breathing assistance in the treatment of pulmonary edema must be individualized as to type and pressure level.

- 4 Alteration in function is effected through the additive (cumulative) action of multiple vector forces producing a given resultant.

#### SUMMARY

A case of acute pulmonary edema occurring during positive pressure inflation of the air channels is presented. The attending ward physicians thought that this resulted from a massive pulmonary embolism. In the absence of many major diagnostic criteria, a different explanation was sought. Analysis based upon physiologic principles that have been known for years seems to support the contention that this complication was the resultant of multiple vector forces acting simultaneously in an additive manner. In the final analysis the condition must be recognized as a complication of intermittent positive pressure breathing.

# Total Pancreatectomy for Chronic Relapsing Pancreatitis and Calcinosiis of the Pancreas

O'NEILL BARRETT Jr, *Captain MC USA*  
WARNER F BOWERS *Colonel MC USA*

**T**OTAL pancreatectomy has been shown to be a practical procedure in the treatment of certain types of pancreatic disorders, including some cases of carcinoma of the pancreas, islet-cell adenoma, and chronic relapsing pancreatitis with or without calcification.<sup>1</sup> Although the technical difficulties of the procedure have been satisfactorily overcome, physiologic problems have been produced, some of which are incompletely understood. Some 40 cases of total pancreatectomy have been recorded in the literature and from these has been gleaned valuable information concerning the metabolic changes which are produced together with their method of management. However, as Waugh and associates<sup>2</sup> pointed out, many patients, young and old, must be observed and studied before final conclusions can be reached concerning the character of diabetic and other changes in these patients. We wish to report another case of successful total pancreatectomy and to discuss some of the metabolic changes noted during a 12 month follow-up.

## CASE REPORT

A 33 year old Negro was first admitted to this hospital on 10 February 1951 for orthopedic treatment of wounds of the right wrist received in Korea. During the period of treatment he developed episodes of "acute gastritis" associated with nausea, vomiting, and epigastric pain. These attacks were mild in nature, responded to conservative therapy and were usually associated with ingestion of alcohol. Serum amylase, urinalyses and two gastro intestinal roentgenographic studies were reported as normal. Following discharge from service, the patient had repeated similar episodes which did not require hospitalization. In February 1954 the patient was seen in a Veterans Administration outpatient clinic where glycosuria was found and a diagnosis of diabetes made. The condition was mild and easily controlled by diet alone.

On 8 April 1954 the patient was rehospitalized at this hospital because of right upper quadrant and epigastric pain with radiation to

---

From Brooke Army Hospital, Fort Sam Houston, Tex. Col. Bowers is now assigned to Tripler Army Hospital, Territory of Hawaii.

the back of two days duration. There was no associated nausea, vomiting, hematemesis or icterus. He also gave a history of a 30-pound weight loss and increased frequency of micturition during the 6 months prior to admission. His attacks of pain had become so severe, disabling, and of such frequency that he was no longer able to hold a job. Past history revealed a moderate intake of alcohol for several years. There was no family history of diabetes or other significant illness.

Physical examination showed a thin man in acute distress. His height was 5 feet 7 inches, weight 118 pounds, temperature 98.6, pulse rate 74 per minute, and blood pressure 118/74 mm Hg. Significant findings were limited to the abdomen. There was no distention or rigidity, but definite tenderness to palpation in the epigastrium and right upper quadrant with voluntary guarding was noted. No organs or masses were felt, and peristalsis was normal. The remainder of examination revealed normal findings except for healed scars of the right wrist and hip. Routine laboratory studies and urine sugar were normal. Serum amylase determinations on three occasions over a six day period were all within normal range. A gastro-intestinal roentgenographic study showed no intrinsic disease but revealed heavy calcification in the region of the pancreas (fig. 1). The gallbladder was barely visible on a cholecystogram.

Figure 1 Heavy diffuse calcification of the pancreas throughout its entire extent

On 22 April the patient was taken to surgery where the pancreas was exposed following division of the gastrocolic omentum. The organ was found to be hard, nodular, and pale with marked edema of the surrounding tissues. The spleen was removed because a severe and extensive fibrous reaction made it technically impossible to identify

and spare the splenic vein. When the lateral and diaphragmatic attachments of the spleen had been divided together with the vessels to the greater curvature of the stomach, it was possible to move the spleen anteriorly and thus carry out the posterior dissection more simply. The splenic vein was ligated at its junction with the mesenteric vein to form the portal vein and the splenic artery was ligated at the celiac axis. The pancreatic ducts were exposed and ligated. Dissection of the pancreas from the portal vein was extremely difficult because of dense adherence. The common duct could not be located even when the lateral attachments of the duodenum had been divided nor could it be identified even when the duodenum had been opened and a rigid probe had been passed up the duct through the papilla. Consequently, the pancreas was "carved" off of the medial aspect of the duodenum leaving a rim of fibrous tissue around the probe when it eventually could be palpated. The blood supply to the duodenum was not disturbed so that no interruption of the gastro intestinal tract was necessary. The entire pancreas was then mobilized and beneath the head a small pseudocyst was found. Pancreas, cyst and spleen were removed *en bloc* (figs. 2-4). A T tube was placed in the common duct and the abdomen was closed bringing the T tube out through a lateral stab wound for external drainage as a precautionary pressure vent.

Figure 2 The tail of the pancreas is densely fused to the hilum of the spleen, which showed passive hyperemia in microscopic section. The normal appearance of pancreas is lost there being no apparent lobulation and the small pseudocyst is seen in the region of the uncinate process.

The postoperative course was entirely smooth with neither biliary, duodenal nor pancreatic leak. The patient had one episode of hypoglycemia on the first day and was maintained on intravenous fluids and regular insulin, the latter not exceeding 25 units per day. By the third postoperative day the patient was given a 2,000-calorie diet and varying amounts of regular insulin, averaging 24 to 36 units daily. On the tenth postoperative day the T tube was clamped for several hours and the patient did not experience any pain or discomfort. Therefore the tube was

left clamped and when a cholangiogram two days later showed normal sphincter function and common duct emptying the T tube was removed without incident or sequelae. On 13 May the patient was placed on

Figure 3. Roentgen examination of the excised specimen demonstrates the diffuse calcification which follows the course of the duct.

Figure 4. Photomicrograph of the pancreas showing diffuse heavy fibrosis with loss of definitive pancreatic tissue. An area of calcification is clearly shown.

30 units of protamine zinc insulin which was changed to neutral protamine Hagedorn (NPH) insulin on 7 June good control being maintained throughout. The remainder of the hospital stay was uneventful except for some right upper quadrant pain following meals

The patient was discharged from the hospital on 25 units of NPH insulin a 2,000-calorie low fat diet, and no pancreatin

The patient was followed in the diabetic and gastroenterology clinics. He did well but added fats to the diet and developed crampy abdominal pain, abdominal distention, and began passing two to four bulky, foul smelling stools per day. He was placed on 3 grams of pancreatin and noted some improvement although he continued to have abdominal distention, especially in the mornings. Although fairly good control of the diabetes was maintained the insulin requirement gradually and progressively increased (fig. 5)

Figure 5 Patient's postoperative insulin requirement

On 7 April 1955 the patient felt ill, and had a 4 plus urine sugar and a blood glucose of 626 mg per 100 ml. He was admitted to the gastroenterology service for further evaluation. Physical examination showed no marked changes from the previous admission except for the presence of marked abdominal distention. The diabetes was brought under control by gradually increasing the NPH insulin to 60 units. Pancreatin dosage was increased to 6 grams per day. Laboratory studies obtained during the hospitalization were as follows: admission hemogram normal; urinalysis showed 4 plus sugar, blood glucose 342 mg per 100 ml; blood urea nitrogen, 23 mg per 100 ml; basal metabolic rate on three occasions, minus 2 minus 13 plus 15. Liver function studies showed sulfobromophthalein sodium retention, 2 per cent bilirubin 1.2 mg per 100 ml; prothrombin time 14 seconds (normal 15 seconds); alkaline phosphatase 10.5 units; cephalin-cholesterol flocculation 4 plus in 24 hours and 4 plus in 48 hours.

and thymol turbidity 10.4 units. Cephalin-cholesterol flocculation and thymol turbidity determinations were done as part of the routine liver studies (although strictly speaking their inclusion among liver function tests may be questioned) and because they showed abnormal levels liver biopsy was performed. The specimen showed only minimal histologic change with radiating cords of typical polygonal cells with well-defined borders and oval to round nuclei with uniform staining quality but with some variation in size and with vacuolation of many nuclei; the portal triads showed a few infiltrating lymphocytes and an occasional polymorphonuclear cell. There was no evidence of fatty infiltration (fig. 6). We were unable to explain the abnormal values of the cephalin flocculation and thymol turbidity. Roentgenograms of the skull were normal.

Figure 6. Photomicrograph of liver biopsy specimen.

During hospitalization the patient showed rapid improvement; the diabetes was well controlled and the abdominal distention almost completely disappeared. After discharge the patient was again followed in the clinic and has done well to date. Caloric intake as far as possible was maintained between 2,200 and 2,400 calories. There was a gradual but progressive gain in weight from an immediate postoperative level of 118 pounds to 127 pounds 14 months later.

#### DISCUSSION

Severe organic tissue change in the pancreas indicates that medical management alone will not give the patient sufficient relief. It was thought that the physiologic damage in the pancreas of this patient (as evidenced by development of diabetes) and the structural damage (as demonstrated roentgenographically by the heavy diffuse calcification) required operative intervention. Operative treatment is limited to attempts at promoting more

July 1957)

# CASE REPORTS—PANCREATECTOMY

1043

effective drainage, ablation of pain, or removal of degenerated tissue. Promotion of drainage by sphincterotomy or anastomosis of the tail of the pancreas to the bowel to allow retrograde drainage did not seem indicated, for although there was diffuse calcification along the duct system, there were no stool changes indicative of a lack of external pancreatic secretion. Ablation of pain by splanchicectomy is not always successful and has the disadvantage of failing to attack the site of tissue change. We prefer a direct attack rather than simply roading retained abnormal tissue less painful. For these reasons excision was decided upon and because the diabetes and diffuse calcification both indicated extensive damage, total pancreatectomy was thought to be the only chance for an acceptable end result. Formerly, it was believed that total pancreatectomy was mandatory. This meant that the Whipple procedure with its disruption of continuity of the gastro intestinal and biliary tracts was necessary. We now know that total pancreatectomy can be accomplished without sacrifice of the duodenum and without necessarily entering the common duct. This permits total removal of diseased tissue by means of a much less radical procedure. Finally, we do not accept the philosophy that all lesser procedures should be tried and proved as failures before the final radical procedure is justified. This would mean subjecting the patient to at least three major operations, which seems too much to require.

In most cases, the insulin requirement following total pancreatectomy has been noted to be relatively low and insulin sensitivity increased.<sup>2-4</sup> Because of this, it has been suggested that in the immediate postoperative period, control of ketosis, rather than the blood sugar level, should be the primary aim. When diabetes exists prior to the time of surgical intervention, the severity of the disease shows more variation. Dixon and associates<sup>5</sup> reported a case in which diabetes, present for four years prior to surgical intervention, remained at about the same severity postoperatively. Pincus and Rutman<sup>6</sup> noted that some patients who had been diabetic previously actually required smaller amounts of insulin after operation. Our patient has shown a progressive increase in the amount of insulin required for satisfactory control.

The nature of the increased insulin sensitivity has been discussed by many authors and several mechanisms have been suggested, including poor nutritional status,<sup>1</sup> disturbances of digestion and absorption,<sup>7</sup> and elimination of the activity of a pancreatic insulin antagonist following operation. It has since been shown that this latter substance is glucagon and is probably derived from the alpha cells of the pancreas. Its function is to raise blood glucose levels by producing glucose from hepatic glycogen.<sup>8</sup> That this substance is actually an adjunct,

rather than an insulin antagonist, was substantiated by Van Itallie, Morgan, and Dottie<sup>6</sup> who showed that peripheral utilization of glucose was enhanced by glucagon. That the absence of such a hyperglycemic agent might be responsible, in part, for the milder diabetes would seem reasonable.

All patients who have had a total pancreatectomy show some impairment of digestion and absorption of fats and protein.<sup>7</sup> Our study did not include stool analysis for fats, but clinically the patient manifested fat intolerance as shown by abdominal distention, discomfort after a fatty meal, and several bulky stools per day. These symptoms were well controlled by the administration of 6 grams of pancreatin per day, which is in keeping with the suggestion by Fallis and Szilagyi<sup>2</sup> that from 6 to 8 grams is usually sufficient.

In experimental work with dogs, Dragstedt<sup>8</sup> demonstrated the development of fatty livers following total pancreatectomy. This could be prevented by the administration of raw pancreas. He believed that this effect was not due to pancreatic enzymes, lecithin, or choline, but to a specific substance called lipocaine, thought to be an internal secretion of the pancreas. Beneficial effects of pancreatin were attributed to presence of lipocaine as well as pancreatic enzymes in this substance. Later studies<sup>9</sup> showed that a lipotropic pancreatic substance either is not required for lipid metabolism in the human being or, if it is required, is supplied in sufficient amounts in the average diet. Honjo and Araki<sup>1</sup> reported that the absorption of fats following total pancreatectomy was better in humans than that noted in dogs and concluded that man retains a better capacity for absorption after surgery than does the dog.

#### SUMMARY

Severe organic tissue change in the pancreas of patients with chronic relapsing pancreatitis indicates that medical management alone will not be adequate treatment. Physiologic damage, as evidenced by diabetes or fat intolerance, and structural damage as evidenced by calcification of the pancreas, require operative treatment. Total pancreatectomy, which can now be accomplished without sacrifice of the duodenum, permits total removal of the diseased tissue. We do not accept the philosophy that all lesser procedures should be tried and proved as failures before total pancreatectomy is justified.

In the case reported, total pancreatectomy for chronic relapsing pancreatitis and calcification of the pancreas was performed. Postoperatively the patient's diabetes showed a progressive decrease in insulin sensitivity, in contrast to the increased sensitivity usually noted. Although no chemical determinations of fat metabolism were made, postoperatively the fat tolerance was greatly improved clinically by the daily administration of

6 grams of pancreatin Liver function studies showed slight aberration after operation A needle biopsy of the liver was performed to rule out fatty infiltration, which has been observed in dogs and suggested as occurring in man No significant histologic abnormalities were noted To our knowledge, this is the first reported histologic study of the liver following total pancreatectomy

# Transverse Aberrant Testicular Maldescent

JOSEPH E DAVIS *Captain MC USA*

**T**ESTICULAR anomalies of position have been classified as undescended and descended.<sup>1</sup> An undescended testicle may be obstructed in its normal anatomic course by mechanical or hormonal factors, in which case it is considered cryptorchid. If it lodges outside of its normal pathway it is ectopic. Anomalies of the descended testicle are inversion in which the testicle is upside down and retroversion in which the posterior surface of the testicle is anterior. Both of the latter conditions are very rare.

The ectopic testicle may be (a) interstitial or inguinal in which the testicle lies anterior to the aponeurosis of the external oblique muscle (b) femoral (crural) in which the testicle lies in Scarpa's triangle (c) pubopenile, (d) perineal, or (e) transverse aberrant. In the last condition both testes descend through the same inguinal canal to the same scrotal sac. Fourteen cases of this anomaly have been reported in the literature. In 1910 Corner<sup>2</sup> observed a 14 year old boy whose left testicle was found within a congenital right hernia. In 1916 Hertzler<sup>3</sup> found both testes and an infantile uterus in the same scrotal cavity of a pseudohermaphrodite. In a case recently reported by Lowsley and Hirwin<sup>4</sup> a 30 year old man had absence of the left testicle from the scrotum, bilateral hernias and perineal hypospadias. During left hernioplasty no testicle was found. During right hernioplasty a small aberrant testicle without an epididymis was found suspended by means of a small vas from the middle of the inguinal portion of the normal right vas. The aberrant testicle contained a malignant dysgerminoma. Lowsley and Forras<sup>5</sup> stated that this anomaly is frequently associated with congenital inguinal hernia, less often hypospadias and presence of a small infantile uterus within the scrotal sac.

## CASE REPORT

A 26-year old man was admitted to this hospital with a chief complaint of swelling and pain in the right groin of one month duration. The patient stated that this began while he was carrying lumber. He had felt something give on the right side of his abdomen near the groin and thereafter noted a bulge into the right scrotum. He

was able to replace this bulge into the abdomen. Pain in the groin was accentuated by coughing and straining. There was no history of gastrointestinal or genitourinary disturbances.

**Post History** The patient stated that he had had no serious illnesses. At age six he fell and injured his left scrotal area. He denied being treated by a physician and he was not hospitalized for this injury. As long as the patient could remember, he had had only one scrotal testicle.

**Family History** The patient was married and had two children. All were in good health and the children had no congenital anomalies. There was no history of anomalous development in the patient's parents.

**Physical Examination** Physical examination revealed a well developed, somewhat obese, man in good health. The ears, nose, and throat were normal. Heart and lungs were normal. The abdomen was moderately protuberant with no palpable masses. Examination of the genitalia revealed a normal penis, normal right scrotal testicle, and a complete right indirect inguinal hernia. The left external inguinal ring was narrow, and a slight impulse was transmitted to the examining finger when the patient coughed. There was no evidence of hernia on this side. A 2 inch, well healed, contracted scar was noted in the left scrotal tissue laterally. There was questionable underdevelopment of the left scrotal tissue. No testicle or cord structures were palpable in the left scrotum.

**Laboratory Findings** The serologic test for syphilis and results of a urinalysis were negative. Hemoglobin was 16 grams per 100 ml. The white blood cell count was 8 000 per  $\mu$ l. A roentgenogram of the chest was normal.

**Course in Hospital** On 31 January 1957, under general anesthesia, exploration of the right inguinal canal was performed. Inspection of the cord structures revealed a congenital indirect hernia, the sac extending around the right testicle. Proximally, the hernial sac was mobilized and dissected away from the cord up to the internal ring. Visualization of the opened sac at this point revealed a sliding component. Mobilization of this component revealed a testicle and associated cord structures, including epididymis and vas deferens. This testicle was one third the size of the scrotal testicle, soft, and separated from its epididymis. Palpation of the mesorchium and the cord structures of this atrophic testicle suggested that they emanated from the left extraperitoneal space. There was no evidence of adhesions or scar tissue surrounding the testicle or cord structures, which might have suggested that this testicle had luxated from the left following the known episode of trauma. The cord of this aberrant testicle could be mobilized easily through the right internal ring. It could be brought down the right inguinal canal easily. Because of their atrophic appearance the aberrant testicle and cord structures were resected. The internal ring was then closed following high

ligation and resection of the bermal sac at its oeck A Bassini type hernioplasty was performed The postoperative course was uneventful A postoperative intravenous pyelogram revealed no other evidence of urinary tract anomalies Microscopic study of the aberrant testicle revealed it to be atrophic there was no evidence of neoplasia in this testicle

### DISCUSSION

In fetal development the gonads form just below the diaphragm A more rapid elongation of the trunk cephalad, in contrast to the slower growing gonad, produces a relative shift of the gonad to a more caudal position At 10 weeks the caudal end of the gonad lies at the boundary of the abdomen and pelvis close to the groin At 12 weeks a sac like protrusion of peritoneum, the vaginal process, evaginates through the ventral abdominal wall producing a short inguinal canal, and at the 7th month passes over the pubis into the scrotum In doing this muscular and fascial layers of the abdominal wall are also carried down and added to what becomes a scrotal sac After the 6th month the testis normally descends along this same path The testis follows the gubernaculum along the inguinal canal The ductus deferens, spermatic vessels, and nerves are carried into the scrotum along with the testis and epididymis

The cause of testicular descent is still unknown The role of the gubernaculum is disputed It has been thought that at the seventh month the gubernaculum stopped in its growth and shortened, thereby drawing the testicle into the scrotum Others say the gubernaculum is too loosely attached to the testis to do this In experimental animals even though the gubernaculum was severed normal descent of the testicle occurred in the majority of cases Evidence suggests that hormonal factors are probably the chief cause of descent

The cause of abnormal descent also is unknown, but the following anatomic factors either singly or in combination may predispose to testicular maldescent (1) an unusually long testicular mesentery which allows the gland undue intra abdominal freedom and renders engagement in the internal ring less likely (2) mesorchial peritoneal adhesions, (3) abnormal persistence of the plica vascularis which may anchor the testis high (4) short spermatic vessels or vas deferens (5) testicular fusion (6) absent, unusually long, or inactive gubernaculum (7) maldevelopment of the inguinal canal—either relative or absolute atresia (8) cremasteric hyperactivity interfering with descent (9) scrotal maldevelopment or absence of a testicular cavity

The role of the gubernaculum may be only to guide or make a pathway for the descent of the testis In rats, when the cranial

nerve was severed prior to eight days of age, failure of testicular descent occurred isolaterally.

In the case reported, the testicle was completely separated from the epididymis. This is a frequent anomaly in the presence of ectopia testis, and is due to failure of urogenital union at the sixth week of development. Congenital hernia associated with ectopia is also a frequent occurrence. It is theorized that in this patient, descent to the opposite internal ring was caused either by aberrant gubernacular attachment and/or a defective left internal ring. It is interesting to note that in dissection of the three month embryo, the testes are in close approximation in their descent, being no more than several millimeters apart.

Operation is the treatment of choice in ectopic testes in order to either replace the testis in the scrotum if possible, or to remove the testis if it is atrophic. Studies have demonstrated a fairly high incidence of neoplasia in ectopic testes. The danger of torsion is also present in a freely movable intra abdominal testicle. Marked separation of the testis and epididymis is also a predisposing factor for torsion of the spermatic cord. Hormone therapy is valueless. The optimum period of time for orchiopexy is up to age eight.

Following demonstration of testicular anomalies it is important to investigate the possibility of other anomalies of the genitourinary and other systems. In our patient, no other anomalies were apparent.

#### SUMMARY

Transverse aberrant testicular maldescent is a form of testicular ectopia. Fourteen cases of this condition in which both testes descended through the same inguinal canal to the same scrotal sac, have been reported in the literature. This anomaly is frequently associated with congenital inguinal hernia and less often with hypospadias.

In the case reported, transverse aberrant testicular maldescent was associated with a congenital hernia and separation of the testicle and epididymis. It is postulated that in this patient, maldescent of the left testicle to the opposite internal ring was caused either by aberrant gubernacular attachments and/or a defective left internal ring.

Three factors make operative intervention the treatment of choice for ectopic testes: (1) the high incidence of neoplasia in ectopic testes, (2) the danger of torsion of the spermatic cord in a freely movable intra abdominal testicle, or when there is marked separation of the testis and epididymis, and (3) the ineffectiveness of hormone therapy. The testis may be replaced in the scrotum if possible, or removed if it is atrophic. The optimum period of time for orchiopexy is up to age eight.

It is important to look for other congenital anomalies when this testicular developmental abnormality is discovered

## ALDOSTERONISM VS PRIMARY RENAL DISEASE

The distinction between primary renal and primary adrenal potassium loss is a matter of great moment for in Conn's syndrome [aldosteronism] removal of the adrenal tumour may bring about complete cure while in primary potassium losing renal disease potassium supplements are the only useful treatment and complete renal failure is the expected outcome Conn's syndrome is to be suspected when there is no history of a primary renal disease when very large potassium supplements fail to lead to the improvements expected and when renal biopsy shows only the tubular lesions of potassium depletion without evidence of other renal disease. If there are signs of an adrenal tumour and if it is possible to demonstrate excessive amounts of aldosterone in the blood or urine the diagnosis becomes easier but if doubts cannot be resolved exploration of the adrenals may be justified

# Multiple Subcutaneous Granular-Cell Myoblastoma

HAROLD A. ALSOBROOK *Lieutenant Commander MC USN*  
JAMES H. LOCKWOOD *Captain MC USN*

**G**RANULAR CELL myoblastoma is generally considered to be a relatively rare benign tumor, most often occurring as a solitary lesion involving the tongue. The next most common site of occurrence is the subcutaneous tissue,<sup>1</sup> in which there is usually an intimate association of the tumor with the overlying epidermis. This association is characteristically represented by pseudoepitheliomatous hyperplasia,<sup>2</sup> which could be interpreted as squamous cell carcinoma. The tumor usually appears in the third, fourth, or fifth decade. Recently Cnve,<sup>3</sup> Kopf,<sup>4</sup> and Vegas<sup>5</sup> reported three cases of multiple myoblastomas occurring in children whose ages were 4, 6, and 8 years. The sexes are equally affected.

Granular cell myoblastoma was recognized as a clinical and pathologic entity after the original publication by Abrikosoff<sup>6</sup> in 1926, who was of the opinion that striated muscle was chiefly implicated in the histogenesis of this tumor. Since that time there have been others who have, by tedious morphologic and histochemical studies, come to the conclusion that granular cell myoblastoma is of neural origin.<sup>7-10</sup>

Malignant granular cell myoblastoma has been reported<sup>7-10</sup> but its incidence, as the literature indicates, is extremely rare. Malignant granular cell myoblastoma arising in the urinary bladder with subsequent widespread metastases and death was reported by Ravich, Stout, and Ravich.<sup>7</sup> Ross, Miller, and Foote<sup>10</sup> reported three cases of malignant granular cell myoblastoma. They were of the opinion that the reported frequency of occurrence of this tumor in a malignant form has been exaggerated by the inclusion of other types of myosarcomas.

The occurrence of multiple, subcutaneous, benign, granular cell myoblastoma nodules is rare, the incidence being about 2.5 percent in a total of less than 250 cases reported up to the present time.<sup>11-14</sup>

## CASE REPORT

A 23-year old white man was well until the spring of 1952 when he first noted a small, nontender, subcutaneous nodule on the ventral aspect of his right forearm. During the following 15 months he developed multiple 7- to 12 mm moderately firm, subcutaneous nodules on the neck, face, chest, both arms, buttocks, and legs. Some of these tumors seemed to be attached to the overlying skin. The nodules were not painful but there was some tenderness when moderate pressure was applied. He had no systemic complaints. His past history and family history were essentially negative. The general physical examination was normal except for the findings as stated above.

The laboratory work was reported as follows: white blood cell count, 7,200 per  $\mu$ l with a differential count of 48 per cent neutrophils and 52 per cent lymphocytes, red blood cell count, 5,560,000 per  $\mu$ l, hemoglobin, 15.5 grams per 100 ml, hematocrit, 54 ml per 100 ml. The urine was normal. The blood Kahn test was negative. The total serum protein was 7.1 grams per 100 ml, albumin 4.9 and globulin 2.2 grams per 100 ml. A roentgenogram of the chest was reported negative. A complete skeletal survey failed to demonstrate any definite roentgenographic evidence of disease of the bones.

## Pathologist's Report

The histopathologic report from the pathology service of this hospital on an excised specimen was as follows: "The sections show skin with multiple circumscribed nodules in the dermis. The latter are composed of large polyhedral cells with a coarse, pink, granular cytoplasm and small, round hyperchromatic nuclei. The cells are regular in size, shape, and staining reaction. No mitoses or giant nuclei are seen. There is a definite relationship between the nodules and peripheral nerves [figs 1 and 2]. At least one of the nodules shows the presence of nerve fibrils in the center of the nodule. Several of the other nodules show nerve sheath cells along the periphery. There is no evidence of malignancy. Acid fast stains of the tissue are negative. Diagnosis: Granular-cell myoblastoma."

From a second excised specimen, Dr. Harlan L. Papenfuss, of Lincoln, Nebr. (formerly on active duty as a pathologist at this hospital) made a series of specially stained slides for study. In reference to the hematoxylin-eosin type stained sections he stated in part:

"In all of the slides within some of these masses [of granular cells] and near their central point, one notes a small bundle of varying length of rather closely packed narrow, spindle shaped cells all running in a uniform direction [fig 3]. In a few areas these bundles of cells seem to be near the periphery of the nodule as if they are penetrating the mass of cells. It is these bundles that I feel are the nerve bundles of nerve fibers. Note that they differ in character from the smooth muscle of the *arrectores pilorum* muscles. With hematoxylin-eosin type staining the contrast is not too great, yet the *arrectores pilorum* muscles appear to have more cytoplasm and less nuclei. Similarly,

Masson's trichrome and a reticulum stain aided little. However, azocarmine stain revealed that the bundles of fibers under discussion stained bluish rather than red orange as did the arrectores pilorum and were therefore, not muscle. A Weil's stain for myelin sheaths showed a blue-black staining of some of the fibers of these bundles, which was interpreted as evidence of myelin and therefore of neural origin."

This set of slides was presented to Dr. Hamilton Montgomery, Section of Dermatology, the Mayo Clinic, for study and comment. Both he and his associate, Dr. R. A. Winkelmann, were impressed by the evidence of nerve involvement but with reservations. Dr. Winkelmann, who has done considerable study in regard to cutaneous nerve endings, stated that although the close correlation between the granular-cell

Figure 3 Another high-power view showing myoblastoma cells with what appears to be part of a neural structure (Hematoxylin-eosin stain, X 420)

myoblastoma cell masses and nerves was the strongest evidence he had yet seen of the neural origin of this tumor. Nevertheless, the nerves themselves appeared normal and had the tumor arisen in nerve that structure should have been destroyed early. Dr. Montgomery was of the same opinion as was Dr. J. Kernohan of the Mayo Clinic, who reported that the tumor appeared to arise from the perineural tissue rather than from the nerve itself.

During hospitalization the patient developed additional lesions, the newer ones occurring on the back of the neck, forearms, and sides of the fingers. A second biopsy specimen of a lesion distant from the first was reported as essentially the same. At the time of discharge

# Porencephaly

THEODORE H. WILSON, Jr. *Commander MC USA*

**T**HE TERM "porencephaly" is controversial. For the purpose of this discussion it means a defect in cerebral or cerebellar structure that appears as a cyst-like cavity. The defect communicates with the ventricles or the subarachnoid space, or, separated from the ventricles by a thin layer of brain tissue, it is covered on the outside by pia arachnoid and filled with a clear, often colorless fluid.

There are many theories of etiology, and considerable literature dealing with the pathology of this lesion. That such cyst-like structures could be of either congenital or acquired origin is apparent. Whether a partial agenesis, a vascular occlusion to some portion of fetal brain, intrauterine trauma of some sort, or intruterine infection can cause porencephaly is speculative. It is believed that birth trauma, subsequent trauma, or severe infections in the brain may produce the condition.

Relatively little has been published concerning the clinical recognition and treatment of porencephaly. Frequently, it is not diagnosed during life, either because there are no symptoms or because the symptoms are attributed to other conditions. The incidental finding of porencephaly at autopsy is not rare. These cystic structures have also been discovered quite unexpectedly during operation or air studies for suspected brain tumors.<sup>1</sup>

An epileptic seizure is the symptom that most often causes a patient with porencephaly to seek a physician's aid. The seizure may be Jacksonian or generalized. Mental retardation, motor weakness, speech defects, visual disturbances, or headache may be other presenting complaints. Symptoms generally are related to the location of the cyst, but the cyst may be huge and yet cause only minimal symptoms.

Findings on physical examination and routine roentgenography of the skull may be entirely normal. Occasionally examination will reveal motor deficits, speech defects, visual disturbances, asymmetry of the skull, mental retardation, or other findings that help in the localization of the lesion. Sometimes roentgenograms

15. Papenfuss H. L. Personal communication.
16. Montgomery H. P. Personal communication.

cause while sleeping he had moaned incessantly, perspired profusely, could not be roused for fully 15 minutes, and was then lethargic and nauseated. His wife thought the patient was having a "seizure," and the ambulance attendant described jerky motions of the patient's legs and rolling back of his eyes. On admission the patient appeared confused and drowsy. He had no headache and there was no evidence that he had bitten his tongue or had had involuntary micturition or defecation. His wife stated that he had had highly spiced food for supper and afterward had two "highballs" but had gone to bed feeling well.

Physical and neurologic examinations revealed no abnormal findings and routine blood and urine tests were normal.

Further questioning when the patient was more alert disclosed that a week prior to admission he had had a boil in the right nostril lanced and subsequently had had swelling of the right eyelids that required antibiotic medication. Repeated questioning disclosed no past history of head trauma. The patient's mother recalled no abnormalities of her pregnancy or delivery. There was no family history of epileptic seizures. Repeated physical examinations showed no abnormalities. The patient was left handed.

Spinal fluid obtained by lumbar puncture was clear, contained no cells, and had a normal protein content. An electroencephalogram had an abnormal pattern and photic stimulation produced a mild right frontal dysrhythmia with delta and theta activity. These findings coupled with the history of a recent virulent infection in the right nostril suggested the possibility of a silent, frontal lobe abscess. A pneumoencephalogram on 16 November 1956 disclosed moderate enlargement but no displacement of both lateral ventricles and the third ventricle. The anterior horn of the right lateral ventricle was blunted. Air was present in what appeared to be a cavity lying just anterior to the anterior horn of the right lateral ventricle and occupying the entire frontal lobe area from the coronal suture forward (fig. 1).

A right frontal craniotomy was done promptly. The bone over the lesion was very thin. The dura appeared normal but beneath it lay a large cystic space filled with clear fluid. This cavity extended from the anterior horn of the right lateral ventricle to the orbital roof and the crista galli. The falx and medial face of the left frontal lobe could easily be seen. There was no identifiable brain tissue forward of the ventricle except for a thin rim of yellowish tissue that arched up over the posterior portion of the cavity forming a partial roof. This was biopsied and proved to be brain tissue. The anterior cerebral artery along with other vessels of uncertain identity could be seen coursing unsupported through the cavity. Inasmuch as it appeared that the cavity communicated with the subarachnoid space, no further procedure was done save to replace the bone flap and suture the scalp. A postoperative roentgenogram of the skull is shown in figure 2.

of the skull show asymmetry of the facial skeleton, with atrophy or bony condensation on the affected side. Evidence of increased intracranial pressure is rare. Pineal shift, unexplained intracranial calcification, or erosion of posterior clinoids may suggest the necessity of further investigation.

An electroencephalogram may assist in lateralizing the lesion, but the diagnosis is made with an air study. The pneumoencephalogram may reveal the defect if there is ventricular or subarachnoid communication. A ventriculogram may show the cyst. Unusual cases have been reported in which a cystic cavity was entered unexpectedly by an exploring needle while searching for a suspected tumor mass.

There probably is not complete unanimity of opinion among neurologists and neurosurgeons as to the advisability of operative therapy of this condition in the first place and as to the type of operation in the second. In a small series of cases, there would appear to have been benefit from operation. The procedure used varies and has included simple incision of the cyst, partial or complete unroofing, total excision when the cyst is surrounded by removable scar, and cystoventriculostomy with or without choroid coagulation.<sup>1-4</sup>

The rationale for doing these operations is hard to explain, but the observed results seem to justify operative therapy. Patients who had epilepsy have been relieved of their symptoms by operation, some for many years, some apparently permanently. It would appear that when porencephaly had developed at birth or soon after, operation did not produce as good results as when the lesion presumably developed in later life, thus permitting other areas of the brain to assume the function of the absent portion. Those unusual cases in which there is increased intracranial pressure are helped by operation, those with mental retardation may show no further deterioration or may even improve.

The following case report illustrates the fact that an individual with a large cerebral defect, presumably originating early in life, may attain a high level of performance and have no symptoms for many years. While this report throws no light on the etiology of such lesions and the follow up is too short to be of any prognostic value, the necessity is demonstrated of a thorough study in all instances of convulsive seizures in an attempt to find a remediable lesion.

#### CASE REPORT

A 28 year old naval aviator with 10 years of active duty involving actual control of aircraft was brought by his wife to this hospital be-

Recovery was complicated only by two brief generalized, convulsive seizures on the fifth postoperative night. The patient was treated with Dilantin Sodium (brand of diphenylhydantoin sodium) and phenobarbital. Recovery was rapid; he was subsequently discharged from the naval service on medication and has resumed academic training for a business career.

### SUMMARY

Porencephaly frequently is first diagnosed at autopsy, or during air studies or operation for suspected brain tumor. This lesion often is not recognized because it may be asymptomatic or its symptoms may be attributed to other conditions.

Mental retardation, motor weakness, speech defects, visual disturbances, and headache may be produced by porencephaly. The patient seeks medical aid most often because of an epileptic seizure.

The findings on physical examination and routine roentgenograms of the skull may be entirely normal. The diagnosis is made by pneumoencephalography or ventriculography.

It appears that many patients with this defect are benefited by operation. The operative procedure used varies considerably.

A case report illustrates that a patient with a large porencephalic defect, presumably originating early in life, may attain a high level of performance and have no symptoms for many years. It also demonstrates the need for thorough study of patients with convulsive seizures.

the United States to stimulate interest on the part of the medical and paramedical public in the care of mass casualties

One of the most far reaching developments in the Army Medical Service's educational program in the past 12 months is the implementation of the new Army wide, military tactical concept of having every soldier a first-aid man, if life is to be saved following a nuclear attack. Through a plan recommended by the Surgeon General of the Army, fully qualified Army Medical Service teams made up of officer and enlisted personnel are now giving basic individual first aid instruction at all U S Army training centers in the United States

Members of the teams are well qualified trainers in first aid, and are chosen for their skill in teaching as well as for their medical knowledge. Plans have been made to train during 1957, 2,100 "medics," the traditional medical aidmen of battle zones, in a 12 week course of concentrated and thorough instruction at the Army Medical Service School

If the beneficial effect of so many young, future physicians receiving instruction in the care of mass casualties along with their study of technical medical topics is certain to be a national defense asset, the new first-aid training concept for the American soldier can have no less an impact on our population. The soldier will return to his home community with more knowledge of how to save his own life or that of his fellows than possessed by any nonmedical soldier since the United States Army was founded

Eight Army Hospitals are conducting a course in acute trauma. This, in addition to providing continuous training for Army medical officers and commissioned ancillary personnel, is also open to civilian physicians and Reserve medical officers in their respective communities

It is anticipated that this year special instructional material in the general care of mass casualties will be issued for Reserve units. The subject is regarded as a part of the over all training in military medicine given to professional officers. Refresher courses that contain material on the medical aspects of nuclear weapons are now held for Reserve officers at the Army Medical Service School three times annually. In addition, spaces are allocated for Medical Corps reservists in the course on management of mass casualties

While this instruction is the central point of the Army Medical Service educational program of preparation, many radii of allied information are being channeled to those who will work beside the physician. Nurses, dentists, veterinarians, and certain mom-

bers of the Medical Service Corps and the Army Medical Specialist Corps will render emergency and definitive medical care commensurate with their abilities. Clinical specialists, aidmen, and hospital corpsmen are being taught to carry a greater share of the professional and logistical load.

There is no substitute for preparation and hard work in any successful large scale endeavor. This is particularly true for medical disaster preparedness. It is absolutely essential for civilian physicians to plan and program their medical civil defense responsibilities. There is a wealth of practical application and valuable information to be gained by civilian medical groups from the experience of the Army Medical Service in the management and care of mass casualties following a nuclear attack upon this nation.

---

#### MEDICAL ORGANIZATION IN NUCLEAR WARFARE

Successful offensive tactics in nuclear warfare depend on the development of small mobile self sufficient tactical elements capable of rapid dispersion and regroupment. Successful defense similarly depends on the development of units that will not offer an easy target for a nuclear weapon; they must be flexible and mobile yet linked by centralized control. The medical support in particular must include casualty treatment units widely dispersed in each community and capable of operating for short periods with communications destroyed. All individuals therein must be trained in first aid for assistance to both themselves and others. Organic medical support attached to tactical units must be as small as possible; all other supporting medical units must be mobile, widely dispersed, and centrally controlled. Rapid transportation must be available. Individuals concerned with medical care must be available for transfer to and from distant areas and they must be under some type of disciplinary control, the nature of which, whether civilian or military, should be decided before the emergency arises. Experience gained from a joint Army and Air Force maneuver in 1955 demonstrated these points but the pattern can also be adapted by civilian communities to the problem of supplying medical care under disaster conditions.

## GROUND BROKEN FOR NEW AIR FORCE SCHOOL OF AVIATION MEDICINE

Ground was formally broken for the new headquarters of the School of Aviation Medicine at Brooks Air Force Base, San Antonio Tex on 10 May 1957. Founded in 1918 at Hazelhurst Field, Long Island, N Y, the School of Aviation Medicine moved to Mitchel Field, Long Island the same year. In 1926 it was moved to Brooks Field Tex, and in 1931 to Randolph Field Tex.

*Major General Otis O. Benson Jr. Commandant School of Aviation Medicine delivering the introductory address at groundbreaking ceremonies Brooks Air Force Base Tex 10 May 1957. To the left is Lieutenant General Dean C. Strother Commander Air University.*

This new aviation medicine research and teaching institution will consist of five modern functional buildings with a central heating and cooling plant. The Research Institute building will house the School headquarters, the Aeromedical Library, and more than 100 individual laboratories. The Academic Building will be able to accommodate over

700 students in six different courses and will be equipped with closed circuit color television. This educational television linked with the Lackland Air Force Base Hospital will enable students to see actual patients and medical technics without leaving their classrooms.

*Symbolic ground breaking of new School of Aviation Medicine. Books Air Force Base Tex. by the Honorable Paul J. Kilday, United States House of Representatives. Watching this ceremony are left to right: Major General Dan C. Ogle, Surgeon General U. S. Air Force and Lieutenant General Dean C. Strother.*

The Flight Medicine Laboratory will accommodate the consultation services and provide space for clinical research in aviation medicine. The Research Laboratory Shops will provide for instrument fabrication.

medical photography and the electronic machines for processing te seatch statistical data The Altitude Laboratory will contain low pres sure chambers simulating the extreme nltitudes required for research in support of tomorrow's aircraft

During the five years spent in designing this establishment special ists in every field of medicine education and research have been con sulted to ensure that it will accommodate and adapt to the needs of the Air Force of tomorrow in the teaching research, and practice of the specialty of aviation medicine

Among those participating in the ceremony were the Honorable Paul J Kilday, United States House of Representatives, who has given the project zealous support in Congress Doctor Melvin A Casberg former Assistant Secretary of Defense (Health and Medical), representing the Department of Defense, Doctor Walter L Biering Chairman of the American Board of Preventive Medicine and Doctor Jan H Tillisch immediate past President of the Aero Medical Association The cere monies were presided over by Major General Otis O Benson Jr, Com mandant of the School of Aviation Medicine while the principal address was given by Congressman Kilday followed by symbolic ground break ing by Lieutenant Genetal Dean C Strother Commander of the Air University Major Genetal Dan C Ogle, Surgeon General of the U S Air Force and Congressman Kilday Other distinguished guests on the speakets platform on this histotic occasion were Lieutenant General John H Collier, Commanding General Fourth U S Army Fort Sam Houston Tex Mayor J Edwin Kuykendall of San Antonio and Doctor James P Hollets President of the San Anxonio Chamber of Commerce and former member of the Armed Forces Medical Policy Council

Visiting military dignitaries from the Office of the Surgeon-Gen tal of the Air Force included Major General Marvin E Kennebe ant for Dental Services Brigadier General Major S White Medical Staffing and Education and Brigadier General Byrnes Director of Professional Services while the major mandas were represented by the following surgeons Brigadier Clyde L Brothers Air Training Command Brigadier General E Lee, Tactical Air Command Brigadier General Albert H Schw berg Air Defense Command and Brigadier General Edward J Trac Materiel Command

Among the distinguished Army officers attending the ceremonies fro Fort Sam Houston were Lieutenant General John H Collier, Command ing General Fourth U S Army Major General Mark McClure, Deputy Commanding General Fourth U S Army Major General William E Shambora MC Commanding General Brooke Army Medical Center, Brigadier General Elbert DeCoursey MC Commandant Army Medical Service School and Brigadier General Dale B Ridgely DC Director of Dental Activities Brooke Army Medical Center

Of the many officers of the Air Force Medical Service who have worked from the onset of this project Colonel Frederick J Frese Jr has been cited for his indefatigable activities during the past five years in directing the planning of the institution and co-ordinating the project activities with various congressional committees and other interested agencies in Washington

### FINDING THE ANSWERS IN AVIATION MEDICINE

One of the interesting aspects of aviation medicine is the manner in which it responds to the challenging problems arising in present flight operations or to those created by considerations of future requirements. Frequently solutions are based upon the fusion of bits of information culled from many basic sciences and clinical subjects having application to the human factors involved in aviation. However where existing knowledge is meager or requires further extension research and development projects are initiated to provide answers. What is perhaps unique in the wide field of medicine is that these answers must be correct for upon them depend many lives and often tremendous economic investments.

## COBALT IRRADIATOR IN CLINICAL USE AT NATIONAL NAVAL MEDICAL CENTER

On 17 May 1957 a new cobalt irradiation therapy unit was dedicated at the National Naval Medical Center, Bethesda, Md. It is the first cobalt irradiation to be placed in clinical use in the Armed Forces and is also the first one in the Washington area. A second unit is at present being installed in the new surgical suite of the U S Naval Hospital San Diego Calif.

*Inspecting the new cobalt irradiation therapy unit are left to right Captain Edward C Kenney MC USN Rear Admiral Thomas F Cooper MC USN Captain S F Williams MC USN and Rear Admiral Bruce E Bradley MC USN*

The cobalt source in the Bethesda unit is of a strength of 500 curies. The unit is to be used in the therapy of selected patients with cancer and will enable delivery of high irradiation dosage levels to deep seated lesions. It is available by arrangement to all members of the Armed Forces and their dependents.

Participating in the ceremony were Rear Admiral Bruce E Bradley MC Deputy Surgeon General U S Navy who accepted the unit for the Bureau of Medicine and Surgery Rear Admiral Thomas F Cooper MC USN Commanding Officer National Naval Medical Center Captain Edward C Kenney MC USN Commanding Officer U S Naval Hospital Bethesda Md and Captain S F Williams MC USN Chief of Radiology U S Naval Hospital Bethesda Md who presided at the ceremony Rear Admiral Charles F Behrens MC USN (Ret) the first Chief of Radiology at the Naval Medical Center in 1942 and later Commanding Officer of the Naval Medical Research Institute also attended the dedication

## NAVY PREVENTIVE MEDICINE UNIT COMMISSIONED AT NAPLES, ITALY

Preventive Medicine Unit Number Seven of the U S Navy was commissioned on 2 May 1957 at Naples Italy in ceremonies attended by high-ranking U S Army, Navy, and Air Force officers, NATO Southern Europe Commanders, and Italian health and government officials. Vice Admiral Charles R Brown USN, Commander, U S Sixth Fleet, sent a message of congratulations to the new unit.

*Rear Admiral Bruce E Bradley MC USN lends a helping hand to Captain Joseph M Coppoletta MC USN as he cuts a cake marking the commissioning of the unit*

Speaking at the commissioning ceremony Rear Admiral Bruce E Bradley Deputy Surgeon General, U S Navy said "The activation of this unit today is the result of a recent reorganization of Navy preventive medicine units throughout the world. These units are our front line forces who fight germs and viruses physical and chemical hazards and other health problems affecting our military forces and their dependents all over the world. Admiral Bradley stated that the current policy of the Bureau of Medicine and Surgery is to have

*Officers and hospital corpsmen of the new unit with Rear Admiral Bruce E Bradley Deputy Surgeon General U S Navy*

its units keep pace with the Navy's modern and rapidly developing forces equipped with guided missiles and nuclear power. The units are equipped to render completely mobile preventive medicine services and are ready to go on a moment's notice. The Deputy Surgeon General lauded the co-operation between the unit and Italian health officials in dealing with problems of mutual interest.

Captain Joseph M. Coppoletta MC USN assumed duties as the Officer in Charge of the new unit. Explaining its purpose, he said "Although our unit is based on land, the zone that is under our control goes from England to the Middle East. Our major customer will be the U S Sixth Fleet with her 25,000 men aboard 50 to 60 ships. It is for them and the thousands of their dependents that we are here to make possible through conferences, films and posters the defense

July 1957)

PRIVATIVI MEDICINI UNIT

1075

of their health and the elimination of sources of possible infection. Captain Coppoletta and his staff of three Medical Service Corps officers and eight hospital corpsmen are ready at any sign of epidemic hazard to reach by air any zone of the coast, from the Atlantic to the Mediterranean where American Military personnel are on duty, or any ship of the Sixth Fleet at sea or in port. Furthermore, the unit offers its services to the NATO forces, and in daily contact with Italian health authorities for a constant exchange of views and programs.

---

## FORMER EDITOR OF JOURNAL RECEIVES DECORATION

Colonel Robert J Benford USAF (MC) who was Associate Editor of this Journal from 1950 to 1953 and Editor from 1953 to 1955 recently received the Commendation Ribbon and Second Oak Leaf Cluster. The medal was presented by Major General Dao C Ogle Surgeon General of the Air Force at a ceremony held in his office (see below)

The citation stated that Colonel Benford had distinguished himself while serving as a member of the Inter-service Committee for Dependents Medical Care. After detailed studies of the problems involved, Colonel Benford made significant recommendations for providing medical care to service dependents in civilian facilities. These recommendations were largely responsible for the enactment of the Dependents Medical Care Act.

The contents are divided into two parts. The first deals with the instruments and technics of perimetry, anatomic considerations and the normal visual field. Each subject is completely covered. The chapter on the vascular supply of the visual pathway is a lucid condensation and that on special perimetric technics clarifies the extinction phenomenon and shows how it may be employed advantageously. Perimetry with ultraviolet radiation and luminescent test objects is developed in a way that is certain to advance interest in this technic.

Part two deals with the interpretation of defects in the visual field and provides a splendid text as well as a full atlas of perimetric diagnostic data. The author's rich background is clearly apparent. The illustrations, diagrams and plates are excellent.

This book will surely become widely used as a text for students of neurology and ophthalmology as well as an authoritative reference work. —EDWARD A. HYAES, Capt. MC USA

THE PROBLEMS OF VISION IN FLIGHT AT HIGH ALTITUDE. AGARDograph No. 13 by Thomas C. D. Whiteside, Ph.D., M.B., Ch.B. Published for and on behalf of The Advisory Group for Aeronautical Research and Development, North Atlantic Treaty Organization by Butterworths Scientific Publications, London. 162 pages, illustrated. Distributed by Interscience Publishers, Inc., New York, N.Y. 1957. Price \$5.

The author has written an excellent summary of the new visual problems we are experiencing in the recent years of high altitude flight. He has accumulated the results of interviews with experienced pilots and has combined these with his own personal experiences at altitudes where most visual problems exist.

Measuring the accommodation of the eyes to determine "space myopia" has been done in a highly satisfactory manner. He has not only used subjective methods but has verified these findings with objective measurements of the accommodative state of the eye. He has shown that accommodative state of the eye. He has shown that accommodation is in constant activity, fluctuating about a level of 0.5 to 2.0 diopters. Because of this accommodation, subjects who were slightly hyperopic had better distant vision at high altitude. Space myopia occurs because of the empty visual field.

"Subjective haze" at high altitude was thought to be due to intraocular scatter or fluorescence. The author shows this is in error; the haze is due to a positive afterimage of the bright cloud floor combined with a low grade anoxia which prolongs the afterimage. He points out the fact that sun glasses are comfortable but visibility is not as good. Using an antiglare visor is nearly as effective in combating veiling glare due to intraocular scatter and does not decrease vision.

This book is highly recommended for all flight surgeons and any one else concerned with visual problems at high altitudes.

—JAMES L. FUELLING, Capt. MC USA

## Reviews of Recent Books

**UROLOGIC INJURIES IN GYNECOLOGY** Including Vesicovaginal Fistula Stress Incontinence and Ureteral Injuries by Henry C Falk M D F A C S A Series of Monographs Obstetrics & Gynecology edited by Claude E Heaton M D 285 pages 97 illustrations F A Davis Co Philadelphia Pa 1957 Price \$7 50

This monograph on urologic injuries is in essence the etiology prevention and management of urinary incontinence in the female It is divided into three sections vesicovaginal fistula stress incontinence and ureteral injuries

A brief history of vesicovaginal fistula with methods of repair are thoroughly described and include vesical fistulas after cesarean section and loss of the urethra Vaginal cystostomy is advocated over suprapubic cystostomy for diverting the urinary stream

Full coverage is given to the medical and surgical treatment of stress incontinence The author's surgical approach with amputation of the cervix or removal of the anterior cervical lip is explained in detail as are the fascial transplant operations and the Marshall Marchetti operation

In the prevention of ureteral injuries the anatomy of the ureter and its relation to pelvic pathology are discussed with justifiable emphasis Should ureteral injuries occur their management is covered at the time of surgery and following the completion of the operative procedure

In this volume Dr Falk completely covers the problems of the gynecologist when confronted with urologic injuries in a readable well illustrated and concise manner He clearly defines policies procedures and techniques which have proved successful for him and his group This volume is a must for the gynecologist of particular value to the urologist and of interest to the general surgeon

—WILLIAM C. HERNQUIST Lt Col USAF (MC)

**THE VISUAL FIELDS** A Textbook and Atlas of Clinical Perimetry by David O Harrington A B M D F A C S 327 pages 234 illustrations and 9 color plates The C V Mosby Co St Louis Mo 1956 Price \$16.

Occasionally while reading through a new textbook the conviction grows with each passing chapter that here indeed is a volume that will become a new teaching classic There are a number of reasons for feeling that this text is one of those few The writing is succinct and easily followed There is maximal information and minimal verbosity

July 1957)

The contents are divided into two parts. The first part deals with the instruments and techniques of perimetry and the second part deals with the normal visual field. Each subject is covered in a separate chapter on the vascular supply of the visual pathway, a chapter on condensation and that on special perimetric techniques, the extinction phenomenon and shows how it may be employed advantageously. Perimetry with ultraviolet radiation and fluorescence of the subjects is developed in a way that is certain to advance interest in this technique.

Part two deals with the interpretation of defects in the visual field and provides a splendid text as well as a full atlas of perimetric diagnostic data. The author's rich background is clearly apparent. The illustrations, diagrams, and plates are excellent.

This book will surely become widely used as a text for students of neurology and ophthalmology as well as an authoritative reference work. —FREDERICK H. HARRIS, Case Western Reserve University

THE PROBLEMS OF VISION IN FLIGHT AT HIGH ALTITUDE. ACADEMIC Press, Inc. No. 13 by Thomas C. D. Whitely, M.D., M.B., Ch.B. Published for and on behalf of The Advisory Group for Aeronautical Research and Development, North Atlantic Treaty Organization by Butterworths Scientific Publications, London. 162 pages illustrated. Distributed by Interscience Publishers, Inc. New York N.Y. 1957. Price \$5.00.

The author has written an excellent summary of the new visual problems we are experiencing in the recent years of high altitude flight. He has accumulated the results of interviews with experienced pilots and has combined these with his own personal experiences at altitudes where most visual problems exist.

Measuring the accommodation of the eyes to determine "space myopia" has been done in a highly satisfactory manner. He has not only used subjective methods but has verified these findings with objective measurements of the accommodative state of the eye. He has shown that accommodative state of the eye. He has shown that accommodation is in constant activity, fluctuating about a level of 0.5 to 2.0 diopters. Because of this accommodation, subjects who were slightly hyperopic had better distant vision at high altitude. Space myopia occurs because of the empty visual field.

"Subjective haze" at high altitude was thought to be due to intraocular scatter or fluorescence. The author shows that this haze is due to a positive afterimage of the bright cloud floor combined with a low grade anoxia which prolongs the afterimage. He points out the fact that sun glasses are comfortable but not helpful in reducing glare. Using an antiglare visor is nearly as effective in combating trailing glare due to intraocular scatter and does not decrease vision.

This book is highly recommended for all flight surgeons and anyone else concerned with visual problems at high altitudes.

—JAMES L. FULLING, Capt. MC USAF

A great deal is known about the liver its functions and its diseases and there is a great body of writing on the subject. However it is beyond the ability of most of us to sift out facts and tenable concepts which can be used in the understanding and treatment of patients with hepatic disease. The authors have done this for us in a thorough detailed and satisfying fashion. With a lifetime of experience in the field of liver disease the authors have produced a text which will make our approach to the patient more rational and knowledgeable though possibly not more effective. They attempt to correlate the clinical and laboratory manifestations of liver disease with the morphologic changes in the liver. At present the correlation is far from satisfactory.

The book begins with a succinct description of the structure of the hepatic cell and of the metabolic processes which take place within it. There follows a discussion of the structure and function of the sinusoids biliary system blood vessels lymphatics nerves stroma and then of the whole organ. Having laid the firm foundation of the normal situation consideration is given to the various pathophysiologic processes which may affect the hepatobiliary system.

The latter half of the book is devoted to description of the various liver diseases and to the effect on the liver of diseases of other body systems. Generous use of cross references permits elimination of repetitious description of previously described basic pathologic reactions. Liver tests and diagnostic methods are thoroughly discussed in a separate chapter. There is an appendix entitled Principles of Diagnosis of Liver Disease Based on Coordinated Use of Functional and Structural Observations.

The book is well printed beautifully illustrated and adequately bound. Two unusual features are very commendable. All of the 3735 bibliographic references are assembled in a section at the end of the volume and arranged alphabetically and there is a seven page addendum summarizing work reported too late for inclusion in the body of the text. This is arranged by appropriate chapter headings and the table of contents lists the addendum and page reference under each chapter where applicable.

This volume should be in the library of each hospital and of each pathologist and internist with special interest in liver disease.  
 —BENJAMIN H SULLIVAN Jr Col MC USA

PHYSIOLOGIC PRINCIPLES OF SURGERY edited by Leo M Zimmerman  
 M D and Rachmael Levine M D 988 pages illustrated W B  
 Saunders Co Philadelphia Pa 1957 Price \$15

Doctors Zimmerman and Levine have done an excellent job of editing and clearing the contributions of the 50 authors thereby avoiding

repetition and wearisome historical verbiage. In this text has been combined much recent work previously available only in journals or monographs. It is an excellent reference text, contains chapters which every surgeon will want to read, and the specialized surgeon will enjoy that portion of the book pertaining to his particular field.

The chapters consider such broad topics as transplantation of tissues, blood transfusions, body fluids and electrolytes, pain and anesthesia, and then proceed to physiology as applied to congenital and acquired lesions of the various organ systems.

While the book is concerned primarily with clinical physiology, this is correlated throughout with embryology, clinical characteristics, laboratory aids, and treatment as required to make a coordinated presentation.

The type is legible, quality of paper is excellent, and the illustrations are clear. References appear at the end of each chapter and are voluminous.

This book is unique since it provides an authoritative reference source in the field of surgical physiology. It should be in every medical library and will probably become required reading for surgeons approaching examination for certification. —DAVID E. THOMAS, Lt Col MC USA

**CLINICAL USE OF RADIOISOTOPES.** A Manual of Technique, edited by Theodore Fields, M. S., F. A. C. R. (Assoc.) and Lindon Seed, M. D., 17 contributors, 455 pages, illustrated. The Year Book Publishers, Inc., Chicago, Ill., 1957. Price \$9.50.

The editors have provided a book containing accepted techniques being used in the field of clinical radioisotopes. The material is excellently presented.

The contributing authors are all well qualified in their field. Although they have selected for detailed description only those procedures which they consider to be most representative of the techniques giving the most accurate results in their experience, a comprehensive bibliography is included at the end of each chapter. The editors are to be complimented on the excellence of the bibliographies which contain references not only to the techniques described in each chapter but also refer to variations of these techniques.

The order of presentation of the various isotopes and procedures used in clinical medicine affords a clear and concise understanding of the field. To complete their presentation, problems concerning requirements of the Atomic Energy Commission, facilities, personnel, equipment, and health physics have been considered in detail, and recommendations have been provided by scientists experienced in these areas. This section, frequently neglected in the literature, is of great value. The appendixes, including a glossary, statistical data, and a record of report sheets, are also of great value.

This manual of technic should be of great value to the physician who uses radioisotopes clinically and should be of equal value to the administrators who are consulted concerning the setting up of radio isotope programs. It is a very worthwhile book for all professional people interested in this field — EDWARD A. LANGDON Lt Col MC USA

**HANDBOOK ON POLIOMEYLITIS** by Joseph Treuta M D D Sc (Hon) (Oxon), F R C S (Hon) (Canada) F R C S A B Kinser Wilson M A M B, M R C P D P M and Margaret Agerholm M A B M B Ch (Oxon) 139 pages illustrated Charles C Thomas Publisher Springfield Ill 1956. Price \$3.75

There is a wealth of pertinent information in this little book that admirably suits the needs of the orthopedist and internist by outlining succinctly for their nonprofessional ancillary help many of the basic precepts that must be adhered to. The book adequately appraises the several views now held on the main problems related to the acute and chronic stages of poliomyelitis. It covers such things as the poliomyelitis viruses, their antibodies, epidemiology of poliomyelitis, factors precipitating frank disease, pathology, clinical description, management of the acute stage, respiratory complications, the transitional and recovery stage, and finally the management of permanent disability.

This makes an excellent and inexpensive reference work for all physicians and is good basic reading for medical students, physiotherapists, occupational therapists, and others interested in the subject — DAVID C. KELLSFY Lt Col USAF (MC)

**CLINICAL DENTAL ROENTGENOLOGY** Technic and Interpretation Including Roentgen Studies of the Child and the Adolescent by John Oppie McCall D D S, F A C D and Samuel Stanley Wald D D S F A C D 4th edition 466 pages 1415 illustrations on 529 figures W B Saunders Co Philadelphia Pa 1957 Price \$10

In this fourth edition the authors have maintained the high standards of presentation evident in the previous editions. Several changes and additions have been incorporated, notably a complete chapter on the long cone technic, rearrangement of the chapters on standard techniques for intraoral and extraoral films, a more complete coverage of the latest data concerning control measurement and effects of radiation, a more complete coverage of temporomandibular roentgenography, and complete studies of the child and the adolescent.

The increasing interest in the long cone technic has brought about equipment changes, increasing the voltage to 90 kvp at 15 ma. The authors present a standardized technic in a thorough manner with excellent photographs of patient and cone position and roentgenographic results obtained.

The section devoted to the production of roentgen radiation and the protective measures necessary gives a concise evaluation of the dangers imminent to all personnel involved in diagnostic and therapeutic

fields New devices for the detection and measurement of roentgen radiation are adequately described and established limits of safety given

The authors devote considerable attention to the important and often neglected diagnostic survey of the child In this section a graphic discussion of the growth phenomena is presented Such features as saturation in the mixed dentition are fully discussed and illustrated Techniques used in orthodontics and in temporomandibular articulation survey are emphasized

The chapters on roentgenographic description of important pathologic changes and the location of impactions and foreign bodies round out a well balanced and well referenced text

The appeal of this book is wide encompassing all associated with diagnostic roentgenographic evaluation and is of particular value to those of the profession preparing for State and Specialty Board examinations —EDWARD R HILDRETH Jr Capt DC USA

**PIONEER SURGEONS OF THE WOMAN'S HOSPITAL** The Lives of Sims Emmet Peaslee and Thomas, by James Pratt May M D 148 pages, illustrated F A Davis Co, Philadelphia Pa 1957

The Woman's Hospital opened in temporary quarters in New York City in 1855, and was chartered in 1857 This centennial volume offers brief lives of the four surgeons, James Marion Sims, Thomas Addis Emmet Edmund Randolph Peaslee and Theodore Gaillard Thomas "whose integrity, intelligence and painstaking efforts made that institution the most potent factor in the development of modern American gynecology" in the judgment of the late Dr James V Ricca

Dr May devotes one section to each biographee Each section is developed in such a manner that it might have stood alone, for in each the biographee is the focus while the other three colleagues are dimly seen There is no final explication of the complex personal and professional relationships between all members of the quarter The history of Woman's Hospital emerges in fragments from the four sketches Some data is necessarily repeated in each section but in general this problem has been skillfully handled The story is an interesting one and has been interestingly and straightforwardly told One wishes that some of the major developments of the period, such as the lagging introduction of anesthesia and the advent of "Listerism" might have been more fully portrayed

The book is replete with quotations from the writings of the four men and from other contemporary documents It is a great vexation that none of these quotations have the source specifically identified The short bibliographies at the end of each section are inconsistent in style and the entries are often inadequate to identify unequivocally the works cited —FRANK B ROGERS Lt Col MC USA

**CORONARY HEART DISEASE** Angina Pectoris Myocardial Infarction by Milton Plotz M. D. F A C P Foreword by William Dock M D 353 pages illustrated Paul B Hoeber Inc Medical Book Department of Harper & Brothers New York N Y 1957 Price \$12

In presenting a completely new text on the subject of arteriosclerotic heart disease the author poses for himself a particularly difficult task. Notwithstanding he has been successful to a remarkably effective degree.

The book is written to appeal to physicians of diverse professional backgrounds and varied primary interests and there is a considerable amount of material that will not be of interest to all readers. At the same time this necessary fault is minimized by a strict isolation of given topics within given chapters and a careful avoidance of repetition.

Many other considerations add to the effective presentation. The style of writing is clear and thoughts are presented in logical sequence. The current bibliography constitutes an excellent compendium of the classics on the subject which have been published in the last ten years. Of special interest is the correlation of presumed divergent concepts in the chapter on lipid metabolism. Clinical evaluation receives careful consideration as do the details of instrumental methods of supportive diagnosis. Medico-legal questions are included as well as the problems of impending infarction and prophylactic management. In general there is no clinically important aspect of the subject which has not been accorded a fair and searching appraisal. The physical form of the volume similarly reflects good organization and attention to deserving detail.

For these few of many good reasons this book is likely to be a much read and appreciated addition to most personal as well as larger medical libraries. —ROBERT B DICKERSON Lt Col MC USA

**RADICULAR SYNDROMES** With Emphasis on CHEST PAIN Simulating Coronary Disease by David Davis B S M D 266 pages illustrated The Year Book Publishers Inc Chicago Ill 1957 Price \$6 50

This brief text describes many radicular syndromes involving primarily the cervical and upper thoracic spine which produce chest pain or other symptoms which simulate coronary artery disease. The material is presented in a brief concise orderly manner and is read with ease. The author describes in adequate detail the various etiologies, the characteristics and locations of the various types of root pain, the sensory and motor signs, the symptoms and the roentgenologic findings seen in the various radicular syndromes. Methods of conducting many of the special examinations which will assist the reader in establishing an accurate diagnosis are described.

The illustrations used include black and white photographs, drawings and charts assist the reader in a better understanding of the material presented. The book is well edited in all respects and the format of the text is good. The bibliography is complete and current and is listed alphabetically by the author. The table of contents is adequate and the text is carefully indexed. The case reports are well selected and concisely presented and these emphasize and illustrate the various syndromes described by the author.

This book will prove to be of considerable value to the medical student, the general practitioner and to a lesser degree to the internist and cardiologist. It will also be useful to many of the other specialties. The general practitioner will definitely profit by having this volume in his library and it is well worth reading by all physicians.

—RALPH D. ROSS, Capt. MC USA

*Principles and Techniques of REHABILITATION NURSING*, by Florence Jones Terry, B. A. R. N. P. T. O. T. R., Gladys S. Benz, R. N. M. A., Dorothy Mereness, R. N. M. A., Frank R. Kleffner, Ph. D., and Deborah MacLurg Jensen, R. N. M. A. (Editor). 345 pages, illustrated. The C. V. Mosby Co., St. Louis, Mo. 1957. Price \$5.50.

This textbook, written by multiple authors, is a nice presentation of the many problems in rehabilitation. The authors, except for one, are all registered nurses who have had considerable experience in this field. Florence Jones Terry, the senior author, is a registered nurse, a physical therapist and an occupational therapist as well. She was former chief nurse at the Institute of Rehabilitation and Physical Medicine, New York Bellevue Medical Center. She calls upon her wide experience in formulating the major portion of this book. While the application of many principles utilized in physical rehabilitation are not always described in detail, there is considerable information in this text. It is certainly a concise and well-written book. It brings the team approach to the problem and highlights the basic philosophy that rehabilitation pays for itself.

I am sure the material on specific conditions, such as hemiplegia, arthritis, et cetera, will prove to be of great value to all interested in these problems. Likewise of considerable interest were the chapters on amputees and "Growing Through Illness." The latter because of the fact that the nurse plays a most important role in individualizing the management of illness in children. If there is any weakness in this book, it is a lack of further, detailed information on the handicapped child. This chapter is adequately covered from a psychiatric standpoint.

This book is recommended to all who are interested in rehabilitation and since each chapter has excellent questions for review as well as references. I believe it is a good textbook for both physical therapists and nurses in training. —EMMETT M. SMITH, Col. MC USA

**PEDIATRIC DENTISTRY** by M. Michael Cohen D M D 607 pages 395 illustrations including 9 in color The C V Mosby Co St Louis Mo 1957 Price \$14 75

This book is a composite of 17 chapters dealing with oral health in children. It is presented by many of the leading authorities in this field. It begins with the embryologic development of the head face and oral cavity and describes the physical and psychologic development of the child.

There is a very informative chapter on craniometry and cephalometry as applied to the growing child and the sections on operative and surgical problems in childhood are excellent. The need for special training and equipment in dealing with handicapped children is lucidly described and its importance with the present population growth is emphasized. The magnitude of this problem can be realized when one considers the fact that there are over 350 000 cases of cerebral palsy in this country. Inadequate dental treatment adds an additional burden to the already handicapped child as well as an additional cost to the parents and welfare organizations.

The photographic reproductions are good illustrate the subject matter well and were carefully selected. The roentgenographic illustrations are clear and have lost only minimal detail in reproduction. The sequence of topics discussed lead to continuity of the text and there is a current and detailed bibliography at the end of each chapter from which the authors have reported the latest developments.

This book has been designed in an attractive and readable form and the type size paper and binding make for ease in reading. The fact that the book is made up of contributions from many outstanding clinicians makes it an excellent reference book for anyone interested in the health and well-being of the child. It is a most worthy contribution to pediatric dentistry a field upon which insufficient emphasis has been placed.—**RICHARD J BURCH Col USAF (DC)**

**SYNOPSIS OF PATHOLOGY** by W A D Armstrong M A M D F R C P F C A P 4th edition 829 pages 328 text illustrations and 12 color plates The C V Mosby Co St Louis Mo 1957 Price \$8 75

The fourth edition of this book brings up to date one of the best texts to date on general pathology.

The title "Synopsis" is misleading because most pathologic conditions are adequately discussed and explained. The photographs mainly in black and white show excellent detail and properly illustrate the text. The references listed at the end of each chapter cover the recent literature and also older classic articles.

This text is highly recommended for anyone interested in general pathology.—**VERNON E MARTEYS Capt MC USN**

PRACTICAL PSYCHIATRY FOR INDUSTRIAL PHYSICIANS by Donald Ross M.D., B.Sc. (Med.) F.R.C.P. (C) Foreword by Robert A. Kehoe, M.D., B.Sc. (Med.) F.R.C.P. (C) Preface by Maurice Levine A.M., M.D. 401 pages Charles C Thomas Publisher Springfield Ill 1956 Price \$7.50

In the foreword to this excellent text Dr Robert A Kehoe, professor of Industrial Medicine at the University of Cincinnati notes that Dr Ross has responded to the need of a new generation of industrial physicians by producing a source book from which they can obtain encouragement, advice and useful technical information. The scope of the applications of psychiatric principles and methods in industrial medicine thus revealed comes as an exciting surprise. Physicians in all branches of occupational medicine, military or non-military will welcome this book in the same spirit as Dr Kehoe.

The author first considers fundamental attitudes and basic techniques which are presented in terms richly interwoven into the occupational setting. The reader is prepared for later material by highly condensed, merry presentations of interviewing and examination diagnosis, psychology and social aids, psychotherapy and physical aids. Problems of neurologic diagnosis and evaluation of mental status are particularly well handled. Special attention is devoted to the criteria for practitioners to determine whether a person requires the services of a psychiatrist, general physician or a social agency. In a section entitled "Cooperation" the author reviews the position of medicine in the industrial social system. Reference is made to the great part played by medical services in the Armed Forces in developing industrial medicine.

Absenteeism, accidents, alcoholism, disability, motivation, rehabilitation and fatigue receive careful analysis, along with many other subjects to which psychiatric "know how" can make a critical contribution. Psychosomatic disorders including injuries to head and back, neurocirculatory asthenia and occupational dermatoses are very well covered. Dust exposure contains some of the author's previous study of this problem both from a statistical and clinical standpoint. Throughout this discussion of detailed problems, the role of the industrial physician as a participant observer of the problems of executives, foremen, supervisors, and women in industry is defined.

Dr Ross's book is based on his participation since 1948 in the training program for industrial physicians developed by the Kettering Laboratory. The beginnings of this work go back even further into the author's extensive experience in military psychiatry in World War II. There is a distinct challenge to all career military medical officers when the fighting stops: psychiatric lessons have been repeatedly mothballed and forgotten. In this book the author has restructured the hard learned lessons of people at war and applied them to people at peacetime work. Those who read his book will recognize its integrity and permanence. —JOHN C. MEBANE Lt Col USAF (MC)

**NEW AND NONOFFICIAL REMEDIES 1957** Containing Descriptions of Drugs  
 Evaluated by the Council on Pharmacy and Chemistry of the American  
 Medical Association An Annual Publication Issued Under the Direction  
 and Supervision of the Council 582 pages illustrated J B Lippincott  
 Co Philadelphia Pa 1957 Price \$3 35

This annual publication of the Council on Pharmacy and Chemistry of the American Medical Association contains descriptions of drugs evaluated on the basis of available scientific data and reports of investigations. It deals with agents proposed for medicinal or adjunctive use in or on the human body for the diagnosis prevention or treatment of disease.

Descriptions of drugs are presented under nonproprietary names in the form of monographs designed to provide the following information: chemical or biologic identity including pertinent properties actions and uses including associated side effects toxicity and precautions and dosage including routes of administration. Monographs are arranged alphabetically according to their nonproprietary titles and are grouped under chapters according to pharmacologic action or clinical use.

This is the second annual publication under the Council's revised program of operation for evaluation of drugs in which the scope of the book no longer is restricted only to descriptions of drugs having established uses but has been expanded to provide for inclusion of information on all available new drugs. More emphasis on basic information has been accomplished by the elimination of dosage forms and sizes the names of manufacturers and monographs describing ready prepared mixtures of two or more drugs. Forty two monographs have been added for drugs evaluated since the previous edition.

In the opinion of the reviewer this annual publication is a valuable reference for physicians and pharmacists.

—HENRY D ROTH Lt. Col. MSC, USA  
**DISEASES OF THE HEART AND CIRCULATION** by Paul Wood O B E  
 M D (Melbourne) F R C P (London) 2d edition 1 005 pages  
 illustrated J B Lippincott Co Philadelphia Pa 1956. Price \$15

In the first edition (1950) Dr Wood Director of the Institute of Cardiology London sought to maintain a proper balance between man and his instruments between experienced opinion and statistics between traditional views and the heterodox between bedside medicine and special tests between the practical and the academic and so to link the past with the present. The second edition on the other hand is written to elaborate the newer investigatory techniques physiologic concepts plus medical and surgical treatment. The author has succeeded admirably in attaining his objectives.

The text is arranged logically on a physiologic and etiologic basis. Each chapter ends with a fairly lengthy list of references which will be of value to the inquisitive mind. The opening chapters on the chief symptoms of heart disease and physical signs serve as an excellent entrée to the diagnostic and investigative procedures that follow. The

chapter on electrocardiography is succinct and lucid however the British method of mounting the electrocardiogram in relation to the Einthoven triangle tends to slow up the reader trained to analyze tracings by studying limb leads and precordial leads in separate groupings. Although the triaxial reference system is explained in determining the vector axis, no mention is made of the hexaxial reference system which lends itself more readily to vector force analysis. The chapter on special investigations should enable the practitioner to comprehend much of the state of literature in this field. Of the remaining chapters that are written with considerable clarity the ones on ischemic heart disease and hypertensive heart disease are outstanding. In view of Burgess' report in 1956 one might question the prognosis given in uncomplicated benign hypertension. The reviewer concurs with the author that this book is of value primarily for graduates interested in clinical cardiology and can meet the needs of students, general practitioners and specialist physicians in other fields of medicine.

In summary this textbook makes an ideal companion piece to the books of Paul D. White and Charles A. Friedberg.

—ARCHIE A. HOFFMAN Col USAF (MC)

**BASIC FOUNDATIONS OF ISOTOPE TECHNIQUE** For Technicians, edited by Willard C. Smullen M.D. F.A.C.R. 163 pages illustrated. Charles C. Thomas, Publisher, Springfield, Ill. 1956. Price \$4.75.

The editor has attempted to provide a book containing the basic background of isotope technic for medical technicians. As such he has accomplished his mission.

The material presented is based on a series of lectures by accepted authorities given as a course for technicians. The editor states that tape recordings of the original lectures were used as a basis for some of the material. Although this technic is worthwhile in that the presentation is thus pretested as to clarity and understanding on the part of the beginners in isotope procedure, it has the disadvantage of an occasional lapse in orderly presentation of the material. The basic fundamentals presented have been designed for personnel of the technical rather than the professional level.

A good background knowledge for the understanding of the technical procedures in the use of radioisotopes in medicine is provided with clarity and completeness. These procedures are discussed in a general way more to provide background information than to assure a "cook book" type of presentation. The illustrations, some of which are drawn from commercial sources, are adequate.

A glossary and appendix are included. The bibliography, although not extensive, contains most of the classic available literature related to the discussions.

This book provides a source of basic knowledge in a field so far neglected for technicians. As such it is worthwhile.

—EDWARD A. LANGDON LT Col MC USA

## OBSERVATIONS ON INFESTATION BY SCHISTOSOMA MANSONI IN PUERTO RICAN TROOPS

WILLIAMS HAUBRICH *Captain MC USAR*  
ROBERT M WELLS *First Lieutenant MC USAR*

**A**MONG THE most common and important trematodes infesting man is the genus *Schistosoma*. It is estimated that approximately 114 million persons, or 5 per cent of the entire human population, harbor this parasite.<sup>1</sup> The worldwide scope of infestation may be subdivided into three categories according to the species involved, pathogenesis, and geographic distribution.

There are three principal species that infest man: *mansonii*, *haematobium*, and *japonicum*. The cercariae and adult forms of this triad, often called "blood flukes," share a predilection for the portal venous system. The female schistosome deposits her ova within venules draining the abdominal viscera. Clinical disease in the human host results from the granulomatous reaction to the ova which, in essence, are foreign bodies.

The disease produced by the species *mansonii* usually is limited to the intestines and liver, abdominal pain and dysentery are often the presenting symptoms. Of the estimated 29 million individuals infested by *S. mansonii*, about four fifths are Africans. The remainder of the infestation is in the tropical Americas which include Puerto Rico.

---

From the Gastroenterology Service, Madigan Army Hospital, Tacoma, Wash. Dr. Haubrich is now at the Henry Ford Hospital, Detroit 2, Mich.

their native island a year or less. Their occupations prior to entry into service varied widely, and no correlation between infestation and vocation was apparent.

Infestation by schistosoma was demonstrated in 15 (35 per cent) of the 43 patients. Only one of the total group confessed to a prior knowledge of infestation by "bilharzia", the remainder of the group seemed unaware that such a disease as schistosomiasis existed.

Information regarding residence of each subject within Puerto Rico was elicited (fig. 1). Of the 15 infested individuals, only 3 claimed the large urban areas of San Juan and Ponce as their

Figure 1 Topographic distribution by prior residence of 43 subjects among the cities and villages of Puerto Rico. X denotes an infested individual and O denotes a noninfested individual.

homes. However, when viewed in the light of the island population as a whole and the number of noninfested individuals from the hinterland, no remarkable correlation between residence and infestation is apparent.

No patient in this group had complaints that could be directly attributed to schistosomiasis. There was no significant difference between the incidence of infestation among those patients admitted to the hospital because of digestive symptoms and that found among those admitted because of unrelated injuries and illnesses. When present, digestive complaints were protoan and nondescript, e.g., anorexia or sitophobia, and postprandial nausea.

The general physical examination gave no clue that infestation existed. In none of the group in whom liver biopsy revealed focal granulomas was the liver palpably enlarged. No splenomegaly was encountered.

In the majority of subjects the hemogram was within normal limits. Eosinophilia of slight to moderate degree was common.

ally recorded with eosinophilia, however, there was almost invariably evidence of infestation by parasites other than *S. mansoni*. Notably these parasites included hookworm, whipworm, and strongyloides in various combinations. There was significant anemia in only one of the patients studied.

In four of the infested individuals a similar, although hardly pathognomonic abnormality in the rectal mucosa was observed by sigmoidoscopy. This consisted of a patchy, fine granularity in which small, punctate hemorrhages were elicited with only gentle swabbing (fig. 2). Except for its patchiness, this change

Figure 2 Photograph taken through the sigmoidoscope of rectal mucosa laden with granulomas of *S. mansoni*. The surface was faintly granular and punctate hemorrhages were induced by gentle swabbing.

resembled that observed in early idiopathic ulcerative colitis. The mucous membrane of the rectosigmoid segment appeared grossly normal in the remaining three fourths of infested subjects, including those in whom the mucosa was laden with microscopic granulomas.

With one exception no other focal lesions were observed within the rectosigmoid colon. This important exception, a 23 year old soldier admitted because of bloody diarrhea, was found to have coexisting granulomatous polyps and an extensive adenocarcinoma of the rectum.<sup>2</sup>

Figure 3 graphically depicts the results of definitive diagnostic studies represented by the triad of coprology, sigmoidoscopic biopsy, and liver biopsy in 15 infested persons. A search of the stool yielded the easily identified ovum of *S. mansoni* in about two thirds of those harboring the parasite (fig. 4). In only

*Figure 3 Incidence of infestation (35 per cent) and results of diagnostic studies among 43 native Puerto Rican soldiers. Sector A represents number of subjects with positive coprology (11); sector B positive rectal biopsies (11); and sector C positive liver biopsies (5).*

*Figure 4 Typical lateral spined ova of S. mansoni recovered from a stool ( $\times 640$ )*

3 patients were ova laden stools the only sign of infestation. In two thirds of the infested group the rectal mucosa contained focal granulomas surrounding the embedded ova (fig 5). In 4 patients the rectal biopsy provided the sole evidence of infestation.

of the affected individuals. Because only patients found to have evidence of infestation were subjected to liver biopsy, we cannot state the number of patients from our group in whom the liver may have provided the only sign of schistosomiasis. There were no instances of frank cirrhosis.

Figure 6. Granuloma induced by *S. mansoni* within liver (Reduced one third from  $\times 900$ )

In four patients the complete triad of positive stool and granulomas in both the rectal mucosa and liver was obtained.

The first eight, or about one half, of the patients in whom objective evidence of infestation was determined were subjected to treatment. Intravenous antimony potassium tartrate, reportedly the preferred therapy,<sup>5</sup> was used alone in six cases. Gaudin was given intramuscularly in one patient in whom repeated venipuncture was not feasible. Another patient received a full course of both drugs. Not only did a course of antimony potassium tartrate impose at least four weeks' additional hospitalization, but invariably the subjective reaction to adequate doses exceeded the complaints with which the patients had originally been admitted. Among those individuals in whom the admitting symptoms might have conceivably referred to organs affected by the infestation, no subjective relief attended the protracted treatment. Therefore, attempts at definitive therapy were abandoned. It should be stated, however, that no significant objective evidence of

toxicity to antimony potassium tartrate (a g myocardial damage) was encountered

### DISCUSSION

The incidence (35 per cent) of infestation by *S. mansoni* in our group of Puerto Rican troops compares favorably with that (39 per cent) reported by Linty and his associates\* in a larger series. Similar observations have been recorded by others.\*

It is obvious that our findings were, for the most part, of a protracted, latent, asymptomatic infestation rather than of a clinically apparent or significant disease. This is not construed to mean that the pathologic changes observed in our 15 patients may not, in time progress to a more grave disease. That schistosomal granulomas in the liver may eventually produce frank cirrhosis is well known. One hazard to these individuals, albeit uncommon, is illustrated in the youth found to have multiple granulomatous polyps studding the rectosigmoid mucosa and coexisting with a rectal adenocarcinoma.

Fortunately, the infested Puerto Rican in the continental United States does not constitute an epidemiologic problem in the sense of transmission or spread of the disease. The essential molluscan host (a snail *Australorbis glabratus*) is lacking in this country. On the other hand, for American troops assigned to the tropical areas where the molluscan host abounds, the possibility of infestation by *S. mansoni* exists. That this does not often occur reflects the apparent requisite for protracted exposure over many months or perhaps years.

The diagnosis of infestation can be established exclusively by no single technic. Under the usual circumstances, coprology provides the simplest screening test and will identify about two thirds of infested individuals. This degree of sensitivity has been borne out by others. Rectal biopsy will reveal a similar fraction in the majority; there is overlapping with both positive stools and biopsies. Histologic examination of the rectal mucosa has the advantage of objectively demonstrating the disease as manifested by the granulomatous reaction to embedded ova. The technic by which unstained mucosal fragments may be immediately examined is eminently useful.

Our experience suggests that attempts at treatment with the present armamentarium of the asymptomatic infestation are unwise. Not only does this therapy necessitate a protracted loss of time from duty (and engender an unwarranted anxiety in the patient) but the currently available drugs induce a high incidence of incapacitating side reactions. Further, the long term value of treatment is debatable.

## SUMMARY

Among 43 young, native, Puerto Rican soldiers, slightly more than one third were found to harbor *Schistosoma mansoni* as manifested by ova in the stools or by granulomas in the rectal mucosa and liver. Almost without exception the infestations were latent and asymptomatic. Active treatment of such disease as encountered in this group is not recommended.

toxicity to antimony potassium tartrate (e. g., myocardial damage) was encountered

### DISCUSSION

The incidence (35 per cent) of infestation by *S. mansoni* in our group of Puerto Rican troops compares favorably with that (39 per cent) reported by Latty and his associates in a larger series. Similar observations have been recorded by others.<sup>1,2</sup>

It is obvious that our findings were, for the most part, of a protracted latent asymptomatic infestation rather than of a clinically apparent or significant disease. This is not construed to mean that the pathologic changes observed in our 15 patients may not, in time progress to a more grave disease. That schistosomal granulomas in the liver may eventually produce frank cirrhosis is well known. One hazard to these individuals, albeit uncommon, is illustrated in the youth found to have multiple granulomatous polyps studding the rectosigmoid mucosa and coexisting with a rectal adenocarcinoma.

Fortunately the infested Puerto Rican in the continental United States does not constitute an epidemiologic problem in the sense of transmission or spread of the disease. The essential molluscan host (a snail, *Australorbis glabratus*) is lacking in this country. On the other hand for American troops assigned to the tropical areas where the molluscan host abounds the possibility of infestation by *S. mansoni* exists. That this does not often occur reflects the apparent requisite for protracted exposure over many months or perhaps years.

The diagnosis of infestation can be established exclusively by no single technic. Under the usual circumstances, coprology provides the simplest screening test and will identify about two thirds of infested individuals. This degree of sensitivity has been borne out by others. Rectal biopsy will reveal a similar fraction in the majority; there is overlapping with both positive stools and biopsies. Histologic examination of the rectal mucosa has the advantage of objectively demonstrating the disease as manifested by the granulomatous reaction to embedded ova. The technic by which unstained mucosal fragments may be immediately examined is eminently useful.

Our experience suggests that attempts at treatment with the present armamentarium of the asymptomatic infestation are unwise. Not only does this therapy necessitate a protracted loss of time from duty (and engender an unwarranted anxiety in the patient) but the currently available drugs induce a high incidence of incapacitating side reactions. Further the long term value of treatment is debatable.

## SUMMARY

Among 43 young, native, Puerto Rican soldiers, slightly more than one third were found to harbor *Schistosoma mansoni* as manifested by ova in the stools or by granulomas in the rectal mucosa and liver. Almost without exception the infestations were latent and asymptomatic. Active treatment of such disease as encountered in this group is not recommended.

August 1957)

*Figure 1 (case 1) Preoperative roentgenographic appearance of cyst*

Microscopic examination of the cyst fragments showed single and confluent cholesterol clefts surrounded almost completely by giant cells of foreign body type (fig 2). The stroma consisted of dense fibrous tissue containing foci of hemosiderin filled macrophages, a few small thick walled blood vessels and masses of hemoglobin. In one portion around a large cluster of crystals, the stroma was very dense, eosinophilic and acellular. Here the giant cells near the clefts were poorly defined and occasionally were trapped in the acellular stroma. At the periphery of the lesion the fibrous tissue faded into and enclosed bony lamellae. The lamellae showed loss of calcium and had only a few osteoblasts. The peripheral bony lamellae probably represented pre existing but modified cancellous bone. Normal well calcified bone and fatty marrow were encountered peripherally. No keratin scales or remnants of epithelium were present.

At last report, four months after operation the patient was on duty without disability and roentgenograms revealed satisfactory healing.

Figure 2 (case 1) Photomicrograph of bone lesion. Note fibrous stroma and cholesterol clefts ( $\times 85$ )

Case 2. A 24 year old man complained of soreness of the left heel. Roentgenogram revealed a cyst in the os calcis. He returned to duty but his heel again became painful, particularly when he had to stand for a long time. There was no history of injury to the os calcis. Six months after discovery of the cyst he was admitted to the hospital where examination of the left foot disclosed no tenderness, swelling or limitation of motion.

Roentgenograms of the left foot and the findings at operation were strikingly similar to those in case one. The cystic area was thoroughly curetted, washed with absolute alcohol and packed with autogenous iliac bone chips.

Microscopic examination of the curetted fragments showed dense fibrous tissue in which there were numerous cholesterol clefts surrounded by giant cells of foreign body type (fig. 3). In the fibrous stroma there were collections of intact red blood cells, hemoglobin and foci of hemosiderin filled macrophages and fat filled macrophages (figs. 4 and 5). The lesion was well circumscribed but not encapsulated. At the periphery there was a rather abrupt change to normal fatty marrow and bony lamellae and a few areas of osteoid tissue. Some of the clefts were surrounded on one side by giant cells of foreign body type, on the other by hemoglobin and a few intact red blood cells. It appeared that as the red cells were lysed they released cholesterol which probably established the foreign body reaction and as hemo-

Figure 5 (case 2) High power view of section in figure 4 ( $\times 170$ )

siderin was formed from hemosiderin it was phagocytosed by the macrophages. Inflammatory reaction was absent and there was no evidence of keratin scales.

Examination one month after operation disclosed a full range of motion of the left foot and no pain on weight bearing. Six months later roentgenograms revealed nearly complete healing with incorporation of the bone chips into the architecture of the os calcis.

**Case 3.** A 21-year-old man complained of pain in the left ankle. Three days before while playing basketball he had turned his left ankle forcing the foot into extreme flexion and abduction. After the injury he had pain, tenderness, and swelling along the fifth metatarsal bone and just anterior to the lateral malleolus. Extreme inversion of the foot was painful.

A roentgenogram of the left foot revealed no evidence of recent injury but disclosed a cyst of the os calcis that had the same appearance as those in cases one and two (fig. 6). At operation the cyst was similar to that in case one and was treated in the same manner. Microscopically the lesion was similar to those in the previous two cases (fig. 7).

Five months after operation the patient was discharged to duty free of symptoms. A roentgenogram at that time showed excellent

August 1957)

## CYSTS OF THE CALCANEUS

healing of the cyst (fig 8) and one three years later (fig 9) almost complete healing (fig 9)

Case 4. A 23 year old man was seen one year after a severe virus twist of the left ankle while playing basketball. Injury was followed immediately by pain and swelling of the ankle and he had considerable difficulty in walking. Three years later the patient had jumped off a 10-foot wall landing on his left heel. There was immediate sharp pain and swelling in the heel that lasted for 2 days. Following this injury and until the present injury, the heel was painful and the ankle swelled after long hikes.

On examination the left ankle was swollen and the lateral side of the joint was tender. Roentgenograms of the ankle (fig 10) showed

Curettage and rongeurium	2	—
Curettage and bone chips	8	4
No operation	7	—
Not stated	4	—

**Age of Patient** The youngest patient was 8 years of age and the oldest, 53. The number of patients according to decades was as follows: first decade, 1, second decade, 5, third decade, 12, fourth decade, 3, fifth decade, 2, and sixth decade, 1. In two instances the age of the patient was not stated.

**Clinical Findings** Often there were no symptoms referable to the cyst. In 3 of our cases, in 4 of Fitte and Mulerhy's<sup>3</sup> cases, and in Pujol Diaz and Autorino's<sup>11</sup> case, the patients sustained a sprain of the ankle or foot, and a cyst in the os calcis was discovered incidentally when a roentgenogram was taken to determine the extent of the injury. Pain in the heel, which in many instances was aggravated by walking, was a prominent symptom in our cases 2 and 4, and in the cases of Coues,<sup>1</sup> Smith,<sup>2</sup> Caritat,<sup>4</sup> Ravelli,<sup>15</sup> and Verstandig.<sup>11</sup> McLachlin's<sup>7</sup> patient was an 8 year old girl who had a painful limp of 1 year's duration. Seven years after operation, she had slight pain in the foot only after walking long distances.

Some of the patients gave a history of trauma. In our case 4, the patient complained of pain in the heel after jumping from a 10 foot wall. For the following 3 years the patient noted that his left heel became painful and swelled after long marches. The cyst was not discovered until he sprained

his ankle Smith's<sup>2</sup> patient fell from a ladder Coues' patient fell on his right heel, and a cyst was found incidentally in the left os calcis Pavolli's patient was a 31 year old German soldier who jumped from a height of 12 feet, with the result that his foot was swollen for 6 weeks, and painful for 6 months Thereafter, he had no disability and was able to march long distances Six years after the injury, a cyst of the os calcis was found incidentally by roentgenography It should be emphasized that trauma may antedate the discovery of the cyst by months or years

Fitte and Mulcahy's case 1 was a 32 year old man bitten by a snake below the external malleolus The area was cauterized with a hot iron and a scar formed Ten years later, the patient sprained his ankle and roentgenography revealed a typical cyst of the os calcis under the scar There is probably no relationship between the cyst and the snake bite

The caso described by Pujo-Diaz and Autorino was unique in that the cyst was located in the large tuberosity of the calcaneous The patient had fallen from a ladder 10 years prior to operation and had sustained a sprain of the left ankle He was unable to walk because of pain in the calcaneus

Physical findings were of little aid in diagnosis In several of the cases there was tenderness of the external malleolus, or at a point just below and anterior to the external malleolus

**Roentgenographic Findings** In all but 1 of the 22 cases reported in the literature and in all of our cases, the cysts were located in the antero-inferior and lateral regions of the os calcis The cysts were oval, round or somewhat triangular in shape with the base directed inferiorly The margins were smooth well defined, and in most instances surrounded by a border of sclerotic bone All the cysts were solitary and unicameral Ridges of bone on the inner surface of the cyst appeared as trabeculations in the roentgenograms and gave a false impression of multiloculation The cortex was not expanded, but was thin over the lateral and inferior aspects of the cysts

The reason advanced for the location of the cysts in the subastragal portion of the os calcis is that in this area there is normally an area of rarefaction Thus, Fitte and Mulcahy mentioned that in their experience the cysts were located anteriorly, between the body and the large apophysis, at a point in the os calcis where there normally exists an area of rarefaction of the osseous trabeculae which correspond to the lines of force Ravelli described this area as *Neutral Raum* (neutral room), or *Fersenbeindreieck* (triangle of the os calcis) and Caritat, as *un punto debil* Surry<sup>3</sup> studied this triangle of rarefaction in 1200 roentgenograms of the normal foot and found

the rarefaction to be marked in 7.1 per cent, moderate in 22.1 per cent, and slight in 70.8 per cent. Brailsford<sup>17</sup> stated that an area of triapular osteoporosis is sometimes seen in the os calcis, that it varies in size, definition and contrast, and that it does not represent an active lesion. In his figure 175A, he illustrates such an area which does not differ roentgenographically from our 4 cases of bone cysts and those reported in the literature. As emphasized by Stuelke,<sup>18</sup> it is difficult to determine in many instances if one is dealing with a bone cyst of the os calcis or with an exaggerated area of normal rarefaction.

Brailsford's<sup>17</sup> figure 176 is a roentgenogram of a cyst, which encompassed nearly the entire os calcis, and had an area of osteosclerosis at its posterior margin. This cyst was the largest described in all the published cases.

Pujo-Diaz and Autorino's case is unique in that the cyst was located in the tuberosity of the calcaneus.

**Operative Findings.** In all our cases, when the cysts were opened at operation, a fluid escaped that was clear or slightly turbid, yellow, and occasionally serosanguineous. The walls of the invariably unicameral cysts were smooth, and showed bony ridges. The cysts, in addition to the fluid, contained a small amount of soft yellow brown tissue filling from 20 to 40 per cent of the cavity. Occasionally bony spicules could be palpated in the tissue. In our case 4 the tissue showed red hemorrhagic areas. Both Ravelli's case 2 and Cristol's case had fragments of sclerotic bone free in the cavity. No discolorable lining was present on gross inspection in our cases.

**Pathology.** The microscopic appearance of the lesions in our cases was that of fibrosis, old and recent hemorrhage, hemosiderin deposition, and numerous cholesterol clefts surrounded by foreign body giant cells. In 2 of our cases the deposition of cholesterol crystals was a prominent feature. In previously published cases of cyst of the os calcis, cholesterol was mentioned only in the case described by Brailsford. Caplan, Viooli, and Crumrine's figure 1 of case 2, also a cyst appearing to be a cholesterol cleft surrounded by foreign body giant cells. Cholesterol in cysts of bone other than of the os calcis has been described. Thus Latta and Lichtenstein<sup>19</sup> noted cholesterol crystals in 2 of 18 cases of bone cysts. In one of their cases the material consisted of cholesterol crystals embedded in fibrin, and in the other case the tissue included cholesterol crystals, foam cells, hemorrhage filled macrophages, and foreign body giant cells. Latta and Lichtenstein<sup>19</sup> mentioned that large quantities of cholesterol crystals are often present in the tissue spaces of bone cysts. Wilson<sup>20</sup> has also mentioned in a few cases of bone cysts the presence of cholesterol crystals. The large cholesterol crystals in the tissue spaces of the bone cysts in our cases are similar to those described by Latta and Lichtenstein<sup>19</sup> and Wilson.<sup>20</sup>

believe represent pre existing bony lamellae which underwent decalcification and resorption and not newly formed bone

Child<sup>21</sup> recently reported a lipoma of the os calcis, a roentgenogram of which was similar in all respects to the roentgenograms in our cases and in the cases previously reported in the literature. We had the opportunity of examining the sections in Child's case (AFIP Acc No 687100) and noted adipose tissue containing cholesterol clefts but no areas of hemorrhage. His case resembles our case & in many respects. In the third reported case of lipoma of long bones by Nielson and associates<sup>22</sup> cholesterol clefts were absent and the cyst contained only adipose tissue. We suggest that Child was dealing with a cyst of the os calcis rather than a lipoma of bone.

**Pathogenesis** We believe that the pathogenesis of cysts of the os calcis is as follows: (1) fracture secondary to trauma within the cancellous portion of the os calcis at a point of weakness (2) hemorrhage (3) intrasosseous pressure as a result of a hematoma with resultant lysis of bone and the formation of a cyst, (4) reactive bone formation to form a zone of sclerosis around the cyst (5) organization of the hematoma with retraction of tissue to form a remnant of fibrous tissue on the wall of the cyst (6) transudation of a bloody or xanthochromic fluid into the cavity.

It is known that intracancellous fracture may occur with minimal trauma. Mullinger<sup>23</sup> described "insufficiency fracture" of the os calcis similar to "march fracture" of the metatarsals. In Mullinger's cases the fractures were mainly in the posterior part of the os calcis and could not be demonstrated by roentgenography until the healing stage when a linear area of dense bone could be seen at the site or sites of fracture.

On microscopic examination of the remnants of tissue within the cysts there was clear cut evidence of organizing hematoma in the form of fibrous tissue which contained hemosiderin granules, foam cells and cholesterol. Cholesterol crystals are a frequent accompaniment of hemorrhage particularly when the adjacent tissue is poor in resorptive capabilities. For example, cholesterol crystals are frequently found in intraocular hemorrhage—a situation in which lymphatics are lacking. Ayres and Haymaker<sup>24</sup> also noted massive deposition of cholesterol crystals following hemorrhage into the choroid plexus of the brain, where lymphatics are likewise lacking. The cholesterol is probably derived from the blood plasma and from the stroma of red blood cells.

The thought that bone cysts are secondary to hemorrhage is by no means new. Beneke<sup>25</sup> in 1904 expressed the opinion that bone cysts were the result of intracancellous fracture which disturbed intrasosseous pressure relationships and these to-

gether with the poor resorptive properties of bone, caused the formation of a cyst. According to Pommer,<sup>24</sup> massive bleeding into bone, serous exudation into a hematoma with increased pressure, and occlusion of venous return may give rise to the formation of a cyst. Pommer also made the important observation, that if the cortex is fractured, a bone cyst does not develop, because the pressure within the hematoma is relieved through the break in the cortex. Copleman and associates advanced the view that bone cysts of the os calcis represented a dysplasia following multiple episodes of minor trauma. Numerous authors have reported traumatic bone cysts in the jaws.<sup>25-27</sup>

Alterations in blood cholesterol is probably not of etiologic significance, inasmuch as the total blood cholesterol and cholesterol esters were within normal limits in 3 of our 4 patients.

Another possibility is that the cysts are secondary to an epidermal cyst of the os calcis, a type of cyst that also contains cholesterol crystals. This possibility can be readily ruled out, however, since epidermal cysts have a squamous epithelial lining and invariably contain keratin, a substance notoriously difficult to mobilize in tissues. In none of our cases and those described in the literature was there evidence of an epidermal cyst.

There was no suggestion of a hemorrhagic diathesis in our four patients, all tests were negative in one of our patients who was completely studied in this regard. The bone lesions in cases of hemophilia do not represent true bone cysts. Ghormley and Clegg<sup>28</sup> described hemophilic pseudotumors of bone in which there were tumors of soft parts and often subperiosteal hemorrhage with extensive bone formation and destruction. These findings are far different from those in cyst of the os calcis.

**Treatment.** The treatment of choice is curettage of the cyst wall and packing with bone chips. Operation had not been performed on some of the cases previously published because the cysts were asymptomatic or because the physicians believed that the cystic area was an exaggeration of the normal triangular area of osteoporosis. We saw two other patients at the U. S. Naval Hospital, Yokosuka, Japan, which were not operated on, because the cysts were asymptomatic. Copleman, Vidoli, and Crimmings treated 2 of their cases by curettage and rongeur of the ridges of bone within the cyst. They stated that bone chips may be placed within the cavity at operation but, are not necessary to effect a cure.

#### SUMMARY AND CONCLUSIONS

Although we have been able to find only 22 cases of cyst of the os calcis in the literature, this lesion probably occurs more frequently than the number of reported cases would indicate.

We have seen 6 patients with such cysts in the last nine years (4 of which are reported in this article) and there are 13 recorded at the Armed Forces Institute of Pathology

These cysts have considerable military significance, in that they may be expected to occur in active young men undergoing rigorous physical activity during military training. There often is no history of antecedent or remote trauma. Symptoms may be absent, or there may be pain in the heel. The diagnostic roentgenographic appearance is that of a well defined, trabeculated, unicameral, solitary cyst in the lateroinferior portion of the anterior half of the os calcis. At operation a yellow fluid escapes, revealing a cyst that is partially filled with a soft yellow brown tissue. Histologically, this tissue shows organizing hemorrhage, often associated with massive deposition of cholesterol crystals. The treatment of choice is curettage and packing with bone chips. This results in a cure within four months, in most instances.

We believe that the cyst is caused by hemorrhage into the bone, secondary to traumatic intraosseous fracture.

**ACKNOWLEDGMENT** We wish to thank Helen Knight Steward of the Armed Forces Institute of Pathology for editorial assistance and Dr Philip Guarino for assistance in translating articles from the foreign literature.

## DELUSIONS OF GRANDEUR

A PHYSICIAN recently remarked that he had been living in a pink cloud. He worked long hours, gave his family a little of his company at mealtimes, let his secretary keep the books and pay the bills periodically, while he kept drifting with the cloud.

There are several errors in this schedule not the least of which is absence of a schedule. In the first place, when a physician starts practice, he should ask himself what he wants out of life and map a course accordingly. If he wants only money, he can work many hours longer than the accepted 40 a week, adopt sound if not ruthless business methods, and keep in close personal touch with his finances. If he wants solely to work and there are patients available, he can extend himself night and day from humanitarian motives, because of restlessness, or just hustle around for the exercise. Most of us are constantly attempting to combine several of these issues by effecting a compromise of one sort or another.

These compromises involve many factors: the first being an inventory of assets in regard to education, training, personal fitness, and expectancy of life. A likable fellow, even if only halfway accomplished medically but with a knack for making money, can build a tidy estate. But there is neither economy nor sense to spending \$30,000 or more for an M.D. (cost plus what could be earned those school years) and upwards of 10 years in classroom and hospital then working 16 hours a day, seven days a week, only to die prematurely from a coronary. Somewhere there should be a compromise which will allow the physician to refuse patients care if it conflicts with the conduct of a safe sane and longer life.

The pink cloud is a delusion in which most physicians revel when they quote income (to themselves or others). This quoting is more frequently practiced by intimation or giving the appearance of affluence.

The fellow who does \$30,000 worth of work a year and gives the public the impression he is making \$30,000 a year is going to pay taxes all along the line for what he has done for himself or his estate. Hospitals and other charities will clamor for handouts. His family will eat and dress at \$30,000 standards and

---

his children will go to expensive schools. Sometimes his wife, who should protect him for her own social security, if for no other reason, will urge him on to work harder because of pride, envy, vanity, or her own sloth.

Of course, doing \$30,000 worth of business doesn't at all mean having \$30,000 to live on. To do \$30,000 worth of work a year, a physician would have to charge an average of \$15 per hour for a 40-hour week for 50 weeks a year, theoretically. To budge these figures very much would mean taking liberties with published statistics of reasonable accuracy, or it would mean working longer hours more days. This in turn exacts its toll of wear and tear on the physician's physique, and deprives him of normal family life, time to pursue avocations, and to indulge those pursuits that make for a well rounded normal citizen of his particular social status. Without these considerations he does not compromise but is compromised.

### BIG BUSINESS

The delusion may show itself in boasting, keeping up with Dr. Jones, or in many trifling ways, but \$30,000 worth of work, particularly if it is made by house calls and office visits, gives the impression of big business. Percentages of collections, however, (amount of money taken in per year in relation to the value of the work done in that year) vary from season to season and from year to year from 50% to 95%, with few exceptions. Over a 25 year period, it is not likely to exceed 90%. This gives a cash income of \$27,000 or less. Depending upon the physician's type of practice and mode of living, his operating expenses can be safely estimated to run not less than 40%. Sixty per cent of \$27,000, then, or \$16,200 represents take home pay before taxes.

From this figure one should deduct the expenses that a physician has over and above those of the ordinary worker, whose taxes are deducted from his pay before he gets it, and whose way of life is geared to actual cash in hand, and not to a paper mirage. This amount is impossible to pin point, but if it includes federal and state taxes, special insurance costs, and a grab bag called noblesse oblige, it would not likely be less than \$5,000. The net comparable earnings for the physician who does \$30,000 worth of work would then be close to \$10,000-\$12,000. The rub comes when the pastor expects church support to be on a \$30,000 level. The rub comes when the hospital thinks the doctor is loaded. The rub comes when the physician wishes to retire or has to, and there has been too little put aside comparable to the other fellow's social security.

Somewhere in the accounting one has to reckon with work done for which no charge is made. This work adds to the fatigue

## DELUSIONS OF GRANDEUR

# TERMINAL CARCINOMA OF THE BREAST

## Palliative Therapy With Depo Testosterone

CARL G PETERSON Jr *Captain USAF (MC)*

**T**ESTOSTERONE cyclopentylpropionate (TCP) has been found to be twice as effective as testosterone propionate (TP) in anabolic potency over a comparable period of time<sup>1</sup> TCP is also effective for a longer period TP for 72 hours, and TCP for 2 weeks<sup>2</sup> In order to compare the effectiveness, dangers, side effects, and convenience of these two forms of testosterone in the treatment of carcinoma of the breast, 12 patients were treated with Depo Testosterone Cyclopentylpropionate (brand of testosterone cyclopentylpropionate) The results were compared with those in King's<sup>3</sup> series of 18 patients treated with testosterone propionate

### METHOD

Five hundred milligrams of TCP intramuscularly once every month was arbitrarily chosen as the dosage in this series Hypercalcemia is a danger when giving any form of testosterone to a patient with bone metastases<sup>4</sup> Therefore, such patients were given TP initially so that if they did develop hypercalcemia, the drug could be stopped immediately and its effect would be exhausted within 72 hours This initial course of TP, amounting usually to 250 mg every other day for 10 days, was given in the hospital where the serum calcium level could be determined frequently Each patient was also placed on a low calcium diet beginning a few days prior to initiation of therapy If the patient did well, as they all did, then TCP was used in subsequent therapy Patients with no bone metastases were treated with TCP from the beginning

A low sodium diet, beginning two to three days before the start of therapy and continuing throughout, was prescribed to prevent or minimize fluid retention, observed at times as generalized edema formation<sup>5</sup> and at other times as pleural effusion<sup>6</sup>

of the day and the weariness of the years, and include medical attention to one's family, close friends, professional brethren and miscellaneous others. Few keep figures on these items but it has been estimated at \$3 000-\$5 000 per year. If this is so, the so-called \$30 000 a year man might be worked at the rate of \$35 000.

The physician who works to the tune of \$35 000 who thinks and spends in terms of \$30 000 but actually lives on \$10,000 is deluded indeed.

---

#### MUST WE ALWAYS TREAT THE PATIENT?

When in therapeutic doubt—and in our present state of knowledge that must be often—we readily yield to the fallacious maxim something must be done. Why do we yield so readily? One reason is that in all of us there lurks a power complex—a desire to dominate our fellow men—to order their uprisings and their downittings. Presented with the issue to do or not to do we are hopelessly biased toward action. The defense so often professed that the patient demands action has something to it but at the same time we make little attempt to educate the public in this respect."

—W MELVILLE ARNOTT M D  
in *Lancet*  
p 183 Oct 15 1955

Although the use of a cauterizing agent on plantar warts involves repeated weelly application, it has the virtue of permitting the patient to remain ambulatory and productive. We use bichloroacetic acid. Some favor the use of electrodesiccation, a modality which demands particular care that the operator minimize loss of normal tissue. Because of the relatively greater danger of permanent disability, the use of roentgen ray therapy and surgical excision has been infrequent in our practice. Many ineffective forms of injection therapy have been described. Despite their present drawbacks, the eventual development of a specific agent would seem likely.

The use of 10 to 25 per cent podophyllin in tincture of benzoin has become the treatment of choice for condylomata acuminata. In extensive lesions, initial treatment is confined to small areas. Widespread inflammation may follow excessive application, particularly when lesions are treated in the urethra, vagina, or anus. The patient should be advised to bathe the treated area after 4 to 12 hours, depending on his response to a trial application.

### SUMMARY

Fewer than 10 dermatoses constitute about three quarters of the dermatologic conditions commonly encountered in either a military or civilian clinic, and the relative frequency of occurrence in military and civilian patients is roughly parallel. A brief review is presented of the diagnosis and treatment of those conditions most frequently seen at military sick call.

### MUST WE ALWAYS TREAT THE PATIENT?

When in therapeutic doubt—and in our present state of knowledge that must be often—we readily yield to the fallacious maxim something must be done. Why do we yield so readily? One reason is that in all of us there lurks a power complex a desire to dominate our fellow men to order their uprisings and their downittings. Presented with the issue to do or not to do we are hopelessly biased toward action. The defense so often professed that the patient demands action has something to it but at the same time we make little attempt to educate the public in this respect.

—W. MELVILLE ARNOTT M. D.  
in *Lancet*  
p. 783 Oct 15 1955

friction, pressure, moisture, and circulatory response are seldom, if ever, reduplicated

Treatment involves daily unroofing of the vesicles and bulla with complete evacuation of the contents, in addition to the measures outlined above

Chronic scaling ringworm of the feet may spread to the ankles and legs. Often a focus is present in the nails. The hands, wrists, and forearms may be involved, but rarely the trunk. Reactions often are so low grade that the patient considers them "natural dryness" of the skin. Usually such processes are caused by *T. rubrum*. The diagnosis ordinarily is made with ease on microscopic examination of the KOH preparation. If the culture demonstrates *T. rubrum*, the prognosis becomes extremely bleak. Involvement of the nails assures a source of reinfection unless controlled. We use a dental bur to thin the nail to the point of pain, and instruct the patient to thin them daily, using an emery board or knife blade after soaking the nails for half an hour with 20 per cent KOH. The nails are coated with nail polish when dry. This necessarily tedious management of a local, irritant but nondisabling infection has little appeal to patients, other than those whose concern is primarily cosmetic.

Avulsion of the nail is performed if a distorted nail is causing soft tissue damage, but is otherwise noncurative. The uniform presence of spores elsewhere in soft keratin often results in reinfection of the new nail.

Management of the skin involves manual desquamation, when feasible, and the use of ointments. Gradual progression to double strength Whitfield's ointment or 10 per cent salicylic acid may be necessary.

**Dermatophytids.** Allergic eruptions of the hands and feet ("ids") often mimic vesiculobullous types, particularly *T. mentagrophytes* infections, and absolute differentiation cannot always be certain. The presence of hyperhidrosis of the hands in the absence of mycelial elements favors the diagnosis of an "id," particularly if the palms and inner aspects of the fingers are involved.

Like all forms of allergy, "ids," constitute an acquired specific alteration in the capacity to react, mediated through an antigen-antibody immunologic phenomenon. It is not surprising then that the responses of the skin to fungal elements or their products are multiple, nor that any area of the skin surface may be involved. In addition to the vesicular forms, "ids" may be morbilliform, papular, or erythematous. The latter may resemble crysipelas, erythema multiforme, or erythema nodosum. The diagnosis should be one of exclusion, in all but vesicular types. Treatment parallels that of vesicular tinea pedis.

## COMMON DERMATOSES

Aug 1 1957)

or soaks followed by 3 per cent Vioform lotion may have to precede the use of fungistatic agents. Ointments are applied only at night. Lotions and emulsions are used during the day until the patient is graduated to a powder. Desenex (brand of zinc undecate) being one of the most practical nocturnal itching may become one of the most difficult of therapeutic problems, and the use of Eurax (brand of crotamiton) or Tronothane (brand of pramoxine hydrochloride) may be indicated in the presence of eczematous response. hydrocortisone ointment should be instituted.

**Tinea Pedis** Inflammations of the feet are among the commonest of diseases observed at sick call. In many but by no means all of these fungi are present however they may contribute little to the disability. The incidence of true dermatophytosis is high, largely because of the tendency to chronicity and recurrence among susceptible races. This circumstance, which often borders on the near hopeless occasionally breeds an attitude of indifference that changes to concern only when cellulitis and lymphangitis supervene.

The most common inflammation of the foot is seen in intertriginous areas at the base of the toes. Many of these are desquimating and self limited, requiring no treatment if they can be kept dry or the toes separated. Often the bacterial element must first be abolished, and this may be the simplest aspect of therapy. Because most antifungal agents are relatively ineffective other suitable measures also must be used. Debridement and drainage may require exposure to the air along with rest. Suitable soaks are followed by 3 per cent Vioform lotion or a bland fungistatic emulsion, and elevation in hot and humid environments, the patient with hyperhidrosis may have dry foot only when an electric fan is available. Slippers are worn when ambulation is first effected. Local therapy being restricted to emulsion type vehicles. Ointments may be used at night when the patient is fully ambulated but powder is used during the day. As porous a shoe as is possible with a leather sole, is necessary. The patient is advised that his participation in athletic events involving the use of a rubber soled shoe may be followed by recurrence.

**Vesiculobullous tinea pedis** usually is caused by *T. men tagrophytes* or *Epidermophyton floccosum*. Often the entire sole and the nails may be involved. Since the process may be a sensitization reaction, fungi are not always demonstrable, nor need they be when the diagnosis is obvious. Repetitive involvement of the dorsa suggests contact dermatitis despite consistent demonstration of fungi, and the patient must be patch tested to the components of his shoes. The patches should be read after 2, 4, and 7 days before rejecting the possibility of allergic sensitization. Such a test is not absolute, as the factors of heat,

Return for check ups at each *scheduled visit* Preceding this shampoo the scalp thoroughly but do not apply the medication

6 If inflammation of the scalp occurs, make an early appointment Some degree of inflammatory reaction of the affected areas occurs frequently and is probably not an indication for discontinuing treatment

7 In some resistant cases, progress is slow Do not become discouraged when results are not effected within 8 to 16 weeks

**Tinea Barboe** Most inflammatory conditions of the bearded area are pyoderma Ringworm of the beard may be seen among men who work with animals, however, and may assume clinical types similar to those of tinea capitis A kerion of the bearded area is usually caused by *T mentagrophytes* or *Trichophyton verrucosum*, and the treatment parallels that of scalp involvement Spontaneous remission usually occurs in two or three months Follicular types, with pustulation and crust formation, progress to fracture of the hair or its extrusion These forms are characteristically prolonged, as are most infections with *Trichophyton rubrum* and *Trichophyton violaceum* Superficial circinate lesions, which may occur outside heavily bearded areas, usually respond readily to fungistatic or keratolytic ointments

**Tinea Corporis** Ringworm of the glabrous skin is often seen in patients exposed to the disease in other persons or in animals Predisposing circumstances may be a hot, humid environment, poor personal hygiene, or a debilitating condition A number of morphologic variants exist, in addition to the circinate type that has a bull's eye appearance because of healing in the center Most of these are self limited and relatively noninfectious Some trichophytions cause lesions that do not heal in the center, and zoophilic species produce many forms that tend toward chronicity These may resemble granulomas, nummular eczema, vesicular dermatoses, or if plaques occur, psoriasis or seborrhea These often are caused by *T rubrum*, which also may produce granulomatous folliculitis and perifolliculitis

**Tinea Cruris** This is a chronic, intertriginous infection that may spread to the inguinal and perineal regions, the intergluteal sulcus, or the buttocks The appearance of the lesion varies with the organism, the location, and the tendency to miliaria and sweat retention It is influenced by temperature, friction, obesity, and local susceptibility to irritants and sensitizers The lesions usually are brownish or red, and maculopapular Scaling occurs only when the process extends away from the folds, if so, the edges are usually well demarcated It is from these sites that the diagnosis is most easily established, because the scaly border readily demonstrates filaments

Treatment is carried out in accordance with the acuteness of the lesion and the presence of secondary infection Sitz baths

## COMMON DERMATOSES

East 1957

clinical appearance varies according to geographical location the course usually is of only two to four months duration

Tinea capitis caused by *T. men-atropica* is uncommon except in farmers who have domestic animals and the kerion is not distinctive Spread to the scalp from lesions elsewhere is most uncommon

In the southwestern areas of the United States tinea capitis caused by *T. tonsurans* has become a public health threat. It is spread among family members and intimates and the morphology is variable Patches often are indistinct and angular and may contain "black dots" that are the fractured ends of involved hairs characteristically buried in a scaling mantle Chronicity over a period of many years is a distinct possibility although kerion development carries a good prognosis Because of the frequently nondescript character the disease often masquerades as and is treated for other scalp conditions

The antifungal ointments commonly used in treating tinea capitis help to confine the infection but will destroy only ear face pores Although roentgen ray epilation cures practically all cases its use usually is confined to treatment of *T. tonsurans* and *T. tonsurans* infections after the disease has been allowed to stabilize over a three- to four-month period This may be delayed somewhat longer with girls Epilation is usually unnecessary in *M. canis* and *T. men-atropica*'s infection but if performed, a six-month period of stabilization is necessary

The treatment of tinea capitis is facilitated by the use of printed instructions

## Ringworm of the Scalp

Your child has a contagious disease caused by a fungus like organism. The affected hairs become dull and brittle and break off near the roots often leaving bald spots Because the disease is contagious all other children in the family should be examined The following directions should be followed carefully and fully

1 Have the hair of boys cut very short taking precautions to catch the clippings which should be destroyed preferably by burning Papers may be placed over the shoulders back and chest and on the floor to catch the hair The shears on the cutting head of clippers should be sterilized by boiling in water for 15 minutes are use

2 Rub the ointment on the affected areas every morning and in the evening scalp every night It must be rubbed in well

3 Wash the scalp once or twice each week using a d. e. gen. shampoo

4 The child must use only his own comb and brush and must wear a clean stocking cap or disposable paper cap at all times If stocking caps are used they may be cleansed by boiling for 15 minutes

This is a chronic, mycotic infection of the hair in an upper follicle. It has a world wide distribution and frequently occurs in epidemics, being spread from person to person by animals and by fomites, particularly clothing and barber's instruments. It probably is spread by the cushions of theater seats and similar objects in crowded places, when personal hygiene is poor. It is five to ten times more common in boys than girls. The disease usually is caused by one of four fungi, each of which provokes a reasonably distinct clinical picture. The onset is insidious, with slight itching. Involved hairs, which are enveloped by spores, are dull and lusterless and project from a papule that varies in the degree of inflammatory reaction. Eventually, most of the hairs break and areas of partial baldness occur. The baldness usually is temporary.

Confirmation of a presumptive diagnosis of tinea capitis is made by study of the hair with a Wood's light, by microscopic examination, and by culture. Hairs infected with *Microsporum audouinii* and *Microsporum canis* have a characteristic, brilliant blue green fluorescence under Wood's light. Other infections show only faint fluorescence or a dead white appearance.

Microscopic examination of a KOH preparation of the hair will demonstrate small spores that appear to be on the periphery of the hair sheath (ectothrix) in *M. audouinii* and *M. canis* infections. The spores of *Trichophyton mentagrophytes* also are ectothrix in location, but are extremely large. Those of *Trichophyton tonsurans* are large, but appear to be confined within the hair (endothrix). If infected hairs are planted on Sabouraud's glucose agar slants, the characteristic cultural appearance and microscopic morphology aids in establishing the diagnosis.

The lesions of the scalp in full blown *M. audouinii* infections are usually superficial, circinate, multiple, gray patches with little evidence of inflammation. Characteristically the disease is chronic and refractory, lasting well over three months, with infrequent spontaneous involution. In some sections of the country, the course has been described as inflammatory from the outset, with coalescent folliculopustules, forming a boggy infiltrate (kerion) from which hairs are extruded. Apparently this course is incident to allergic sensitization. Despite the severity and chronicity of the condition, the appearance of a kerion is a favorable sign, usually antedating involution and rarely leading to permanent alopecia.

*M. canis* infections run a relatively short course, since a kerion almost always develops. The disease is usually acquired from other children or animals. Kittens are common transmitters, as the fungi may be confined to a few of their peripheral hairs and detectable only by a Wood's light. Here again, although the

clinical appearance varies according to geographical location the course usually is of only two to four months' duration

Tinea capitis caused by *T. mentagrophytes* is uncommon except in farmers who have domestic animals and the kerion is not distinctive. Spread to the scalp from lesions elsewhere is most uncommon.

In the southwestern areas of the United States, tinea capitis caused by *T. tonsurans* has become a public health threat. It is spread among family members and intimates, and the morphology is variable. Patches often are indistinct and angular and may contain "black dots" that are the fractured ends of involved hairs, characteristically buried in a scaling mantle. Chronicity over a period of many years is a distinct possibility, although kerion development carries a good prognosis. Because of the frequently nondescript character the disease often masquerades as, and is treated for other scalp conditions.

The antifungal ointments commonly used in treating tinea capitis help to confine the infection, but will destroy only surface spores.<sup>11</sup> Although roentgen ray epilation cures practically all cases its use usually is confined to treatment of *M. audouinii* and *T. tonsurans* infections after the disease has been allowed to stabilize over a three to four month period. This may be delayed somewhat longer with girls. Epilation is usually unnecessary in *M. canis* and *T. mentagrophytes* infection but if performed, a six months' period of stabilization is necessary.

The treatment of tinea capitis is facilitated by the use of printed instructions.

#### Ringworm of the Scalp

Your child has a contagious disease caused by a fungus like organism. The affected hairs become dull and brittle and break off near the roots, often leaving bald spots. Because the disease is contagious all other children in the family should be examined. The following directions should be followed carefully and faithfully.

1. Have the hair of boys cut very short, taking precautions to catch the clippings which should be destroyed preferably by burning. Papers may be placed over the shoulders, back and chest and on the floor to catch the hair. The shears or the cutting head of clippers should be sterilized by boiling in water for 15 minutes after use.

2. Rub the ointment into the affected areas every morning and into the entire scalp every night. It must be rubbed in well.

3. Wash the scalp once or twice each week using a detergent shampoo.

4. The child must use only his own comb and brush and must wear a clean stocking cap or disposable paper cap at all times. If stocking caps are used, they may be cleansed by boiling for 15 minutes.

**Tinea Capitis** This is a chronic, mycotic infection of the hair shaft and upper follicle. It has a world wide distribution and frequently occurs in epidemics, being spread from person to person by animals and by fomites, particularly clothing and barber's instruments. It probably is spread by the cushions of theater seats and similar objects in crowded places, when personal hygiene is poor. It is five to ten times more common in boys than girls. The disease usually is caused by one of four fungi, each of which provokes a reasonably distinct clinical picture. The onset is insidious, with slight itching. Involved hairs, which are enveloped by spores, are dull and lusterless and project from a papule that varies in the degree of inflammatory reaction. Eventually, most of the hairs break and areas of partial baldness occur. The baldness usually is temporary.

Confirmation of a presumptive diagnosis of tinea capitis is made by study of the hair with a Wood's light, by microscopic examination, and by culture. Hairs infected with *Microsporum audouinii* and *Microsporum canis* have a characteristic, brilliant blue green fluorescence under Wood's light. Other infections show only faint fluorescence or a dead white appearance.

Microscopic examination of a KOH preparation of the hair will demonstrate small spores that appear to be on the periphery of the hair sheath (ectothrix) in *M. audouinii* and *M. canis* infections. The spores of *Trichophyton mentagrophytes* also are ectothrix in location, but are extremely large. Those of *Trichophyton tonsurans* are large, but appear to be confined within the hair (endothrix). If infected hairs are planted on Sabouraud's glucose agar slants, the characteristic cultural appearance and microscopic morphology aids in establishing the diagnosis.

The lesions of the scalp in full blown *M. audouinii* infections are usually superficial, circinate, multiple, gray patches with little evidence of inflammation. Characteristically the disease is chronic and refractory, lasting well over three months, with infrequent spontaneous involution. In some sections of the country, the course has been described as inflammatory from the outset, with coriaceous folliculo-pustules, forming a boggy infiltrate (kerion) from which hairs are extruded. Apparently this course is incident to allergic sensitization. Despite the severity and chronicity of the condition, the appearance of a kerion is a favorable sign, usually antedating involution and rarely leading to permanent alopecia.

*M. canis* infections run a relatively short course, since a kerion almost always develops. The disease is usually acquired from other children or animals. Kittens are common transmitters, as the fungi may be confined to a few of their peripheral hairs and detectable only by a Wood's light. Here again, although the

which may include species of *Candida* (information often useful in treatment and prognosis) one must culture the specimen. This also is a simple procedure. It involves the use of Sabouraud's glucose agar slants at room temperature. Final identification is made on the basis of the characteristics of the colony cultured and its microscopic morphology. By transferring a portion of the colony to a drop of any wetting agent on a slide, teasing it into fragments, then staining with Gram's stain or "cotton blue" its characteristics are clarified. The species identification is described in all texts of elementary mycology.

These texts also will present a discussion of the common contaminants the occasional presence of which may be the most disappointing and limiting feature of this otherwise engaging investigation. All equipment necessary for a final diagnosis can be found on the supply table of the Medical Department. If the dispensary or clinic does not possess an autoclave, an inexpensive pressure cooker will sterilize the medium in 15 minutes at 15 pounds pressure.<sup>11</sup> The tubes or bottles can then be allowed to cool "on a slant" and if refrigerated will be satisfactory for weeks.

The diagnosis of *tinea versicolor* and *tinea capitis* is facilitated by the Wood's light, which uses a nickel chloride filter to eliminate all the rays but ultraviolet from a beam of light. In *tinea versicolor* there is a yellowish tan fluorescence in certain other fungal infections there is a brilliant greenish-yellow or a greenish gray fluorescence. The presence or absence of fluorescence is of great practical benefit in diagnosis and management.

**Tinea Versicolor.** The most superficial common mycosis is *tinea versicolor*, which is characterized by the asymptomatic and chronic course of tan colored desquamating macules usually involving or spreading to the chest, back, shoulders, and neck. The diagnosis is readily apparent except when other portions of the body are involved or the rash becomes follicular in appearance. Because it is so trivial and noncontagious by nature, it is usually disregarded by the patient. He may present himself after acquiring a sun tan because the areas of involvement remain relatively depigmented. The presence of mycelia and spores of varying sizes, on direct microscopic examination, establishes the diagnosis. Culture is not only unnecessary but unsatisfactory. Whereas some patients will be satisfied with reassurance, others will require some form of treatment. All forms of treatment are unsatisfactory, inasmuch as most infections recur, but any fungicide is temporarily effective. Twenty-five per cent sodium thiosulfate lotion applied twice daily is one of the most effective, simple, and least objectionable preparations available. Recently, selenium sulfide preparations have been used with encouraging results.<sup>12, 13</sup>

Local therapy is influenced by the fact that the skin of the lower legs is exceedingly susceptible to sensitization reactions. Only bland wet dressings, lotions, or ointments with low sensitizing index are used. The use of Gelfoam (brand of water-insoluble gelatin base) powder or sponge<sup>24</sup> has been one of the greatest recent advances in therapy.

Sponge rubber also may be placed over ulcers and supported with elastic dressings or an Unna boot, in order to maintain steady even pressure. Inasmuch as many of the organisms of infected cases are anaerobes, culture and sensitivity studies may be helpful. Antibiotics may have to be supplemented by zinc peroxide paste or Vioform. When inflammation and weeping subside, lubricants or tar and hydrocortisone may be used. Following epithelization, Ace bandages or elastic stockings may be indispensable.

The patients should be evaluated by surgeons experienced in vascular physiology. Despite painstaking study, a decision to carry out a surgical procedure on the superficial veins, including multiple ligation and stripping, may prove to be without benefit if deep and feeder veins are incompetent.

#### FUNGAL INFECTIONS

The ringworm fungi (dermatophytes) are ubiquitous, world wide in distribution, and infect both man and animals. The forms carried by the latter are usually transient in man, tending toward spontaneous cure. Because natural resistance is high in the general population, the acquisition of a fungal infection involves unique susceptibility combined with special circumstances.<sup>25</sup> The presence of the disease in members of the same family constitutes the exception rather than the rule, and the average person can be infected artificially with great difficulty, if at all. Since the organisms are common soil saprophytes and are present in great numbers in barracks, dormitories, and shower rooms, such prophylaxis as is commonly practiced usually is inadequate and doomed to failure.

Any diagnosis of a superficial fungal infection based solely on clinical grounds may be wrong as often as right. On the other hand, the establishment of conclusive proof is one of the simplest procedures in laboratory diagnosis,<sup>26-28</sup> and it is unfortunate that it has fallen into such general disuse. One has only to immerse involved hair or a scraping of the skin or nails in 15 per cent potassium hydroxide (KOH) on a glass slide, to establish the diagnosis microscopically. This may be facilitated by adding equal parts of Parker "51" fountain pen ink<sup>29</sup> to the KOH, or heating thick specimens until "clear." The presence of branching septate hyphal fragments in the skin or nails or the presence of spores on the hairs can be determined by any novice. This will confirm the diagnosis, but to determine the genus,

## COMMON DERMATOSES

A. Gust 1957)

**Chronic Eczematous Dermatitis** This condition frequently originates in an area of contact or irritant dermatitis following which secondary factors lead to and perpetuate inflammatory changes. Morphologically any form of dermatitis may be seen and the lesions may be single or multiple without preference as to site or distribution. Inasmuch as the most constant feature is the tendency to recur at previously involved sites seemingly without provocation and to develop exacerbations during therapy previously regarded as adequate, this is often one of the most tantalizing conditions in dermatology.

Once the pattern of dermatitis has been set secondary factors may assume principal roles contributing to chronicity. The patient's sensitivity to topical application is increased and flare ups may defy the blandest of therapy. The effect of trauma, prosuro, sweating, infection or irritation may be magnified, and it may be necessary to discontinue even oral medication. The use of new preparations often must be limited initially to small trial areas. As cross group sensitization has become common, the patient must be warned to suppress an inclination to depart on independent courses of self medication.

The treatment of this entity is similar to that outlined for atopic dermatitis. Because of the cyclic nature of the disease conclusions as to etiology and effects of therapy must be arrived at cautiously and impartially. In patients with tendencies to hypochondriasis degeneration of the doctor-patient relationship into pointless and unproductive detailed discussions of the diet may be avoided by a temporary elimination of those foods that have been incriminated in past experience. Those might include milk, cheese, chocolate, tomatoes, citrus fruits, coffee, shellfish and nuts.

**Stasis Dermatitis** This dermatitis usually occurs about the ankles, but if neglected the inflammation extends, edema increases, and the signs of eczema appear. Cellulitis, recurrent phlebitis, lymphangitis, ulceration, pigmentation and lymphedema presage an irreversible state. Varicose veins comprise the fundamental pathology, and as 75 per cent of varices occur before 30 years of age in 10 to 17 per cent of the population, all medical officers must be prepared to recognize and treat the entity early. It is commonly seen in those who have a familial predisposition and who spend much time "on their feet." Regardless of cause, the derangement in physiology leads to interference with peripheral vascular circulation. Our primary aim is to combat the element of stasis by use of elastic stockings or bandages or by elevation of the extremity for indicated periods. Uninterrupted decompensation leads to extravascular escape of cells and protein, with development of a brawny fibrosis and hemosiderosis.

tropic dysfunction, and many forms of endocrine imbalance, particularly diabetes

In the simple forms, the condition is easily recognizable by excessive oiliness, often with greasy scaling of the scalp or extension to the lids, ears, nasolabial folds, and sternum. With the development of pyogenic superinfection and involvement of the flexures and intertriginous areas of the glabrous skin, the diagnosis may be difficult. This is especially true in the chronic form presenting disseminated and confluent plaques, which may become exfoliative and intractable. Treatment for seborrhea capitis with 3 per cent resorcinol alcohol and detergent shampoos is usually sufficient. Selenium sulfide may be helpful, supplemented by 3 per cent sulfur salicylic ointment, or in advanced cases by compound coal tar ointment. When the lids, ears, or intertriginous areas are involved, the degree of inflammation will indicate the management. Antibiotic lotions, or hydrocortisone with or without 0.5 per cent selenium sulfide, may simplify the therapy.<sup>15</sup> Otitis externa, when chronic, is treated in conjunction with an otologist, who can aid in debridement and promoting dryness of the external auditory canal.

**Nummular Eczema** As the name indicates, nummular eczema is characterized by well demarcated elevated erythematous coin-shaped plaques containing vesicles. The lesions are usually multiple, commonly appearing on the hands, feet, extremities, back, or buttocks. Despite a typical morphology, the patient may not be atopic, and the appearance of nummular eczema after the age of 30, when the eczema of most atopics has subsided, makes it a puzzling entity. Furthermore, a history of contact dermatitis may not be forthcoming, although the lesions may occasionally occur in showers in patients with other forms of dermatitis in whom local or systemic medication of high sensitizing index has been used. That the areas constitute a point of lowered resistance is evidenced by repeated recurrence at sites previously involved. Another fairly consistent finding of some consequence is the presence of coagulase positive micrococci. The significance of this fact has not been established, but these commonly torpid infections must be contrasted with the condition known as infectious eczematoid dermatitis.<sup>16</sup> This syndrome occurs when the appearance of infectious exudate precedes the development of plaques of vesicles or pustules in contiguous areas, often followed by the development of similar lesions at distant sites.

A search for precipitating factors must be diligent and complete.<sup>17-24</sup> Foci of infection, drugs, and ingestants have been incriminated, and their abolition often leads to relief. Symptomatic and general therapy involves correction of dryness, avoidance of irritants, the use of antibacterial agents, and the general measures described above.

as inexpensively as possible and ointments containing tar, salicylic acid, or sulfur used as indicated. Local infection may be controlled with Vioform (brand of iodochlorhydroxyquinin) or antibiotic ointments.

Mixtures of the above with or without hydrocortisone<sup>12</sup> may repay the increased costs involved. Since exacerbations may be triggered by unknown factors, a recurrence that intervenes during therapy of a type usually considered efficacious often demoralizes the patient and he must be prepared emotionally for this eventuality.

Ultra-violet ray therapy often leads to involution, as may roentgen ray therapy. The transient and uncertain benefits and the hazards of the latter must be carefully evaluated, and a proper place assigned to it in the long range plan of therapy.

Superficial psychotherapy in conjunction with tranquilizing drugs may offer much to the patient, whereas extensive discussions with psychiatrists, regardless of their competence, may serve only to vitiate our other efforts. The rapport necessary in the management of the condition usually obviates any indecision in this respect.

In atopic dermatitis in infancy there may be marked variation in the localization of the lesions. Usually the face is involved but areas of varying size may appear at any site. Much of the disease is incident to scratching, and our first efforts at therapy are aimed at prevention of irritation. All surfaces in contact with the skin should be smooth, the clothing should be non-abrasive, and the hands should be kept from the skin by mechanical means. Irritating soaps, detergents and local radiation are temporarily discontinued.

If a flare up of atopic dermatitis is observed to follow introduction of a certain food<sup>13</sup> into the diet, its use should be suspended temporarily. Traditionally, milk, eggs, and wheat have been said to be causative, though incontrovertible evidence for this assumption in the individual case may be elusive.

If one of the many available food substitutes is used, the principles of adequate nutrition must be maintained. The use of antihistaminic therapy is usually effective and well tolerated. If home care is unavailing, the child may have to be hospitalized, and in certain selected cases systemic corticosteroid therapy may be necessary.

**Seborrheic Dermatitis.** This disease is not always included in the eczema group, although many of the features of eczema may be evident. Primarily, it is a disease of excessive sebaceous gland activity and is commonly localized to areas of high sebaceous gland concentration. It may appear in association with acne vulgaris, rosacea, psoriasis, Parkinson's disease,<sup>14</sup> neuro

formity in the nomenclature of this disease had its origin in vagueness of diagnostic criteria. The fundamental pathology of eczema is well known, and although the etiology may remain somewhat obscure, the clinical signs, protean though they may be, are fairly clear cut. They occur in approximately the following sequence, but may regress at any point: (1) inflammation, (2) vesicle or bulla formation, often with serous exudate and crusting, (3) thickening of the skin, sometimes with papule formation, (4) petechial development and hyperpigmentation, and (5) excoriation and lichenification incident to scratching.

**Atopic Dermatitis.** This condition often appears in infancy, but tends to disappear at any age thereafter up to 30 years. The lesions are commonly located on the face and neck, antecubital and popliteal areas, hands, wrists, and ankles, although any site may be involved in exacerbations. Lichen chronicus simplex usually occurs on the face, neck, wrists, and legs, thighs, legs, and occiput—regions that are readily accessible to the patient in moments of concentration or of frustration. Often there are areas of chronic localized infection, particularly in the intertriginous tissues. Sweat retention is common, as are manifestations of vasomotor instability.<sup>10</sup> Pruritus is marked and may occur in waves, precipitating periods of uncontrolled scratching and excoriation.

There usually is a family history of allergy, hay fever, vasomotor rhinitis, urticaria, asthma, or migraine, the classical background of the atopic. Treatment is often prolonged and dissatisfying to patient and physician alike, and must be conducted in an atmosphere of mutual understanding and loyalty. A careful history is necessary, particularly to determine the efficacy of previous therapy and to avoid medication objectionable to the patient. Broad principles should be stressed repeatedly, especially the avoidance of physical and emotional stress<sup>11</sup> and of outright precipitating factors often well known to the patient but ignored during flights of irresponsibility.

Inasmuch as skin testing ordinarily discloses a multiplicity of sensitivities, such an evaluation, if used as a guide in management, is probably best left to the dermatologist.

General antiallergic measures are essential. The skin is highly susceptible to primary irritants, and chemical and physical insult, including that caused by soap, must be avoided. Gloves of cotton, with or without rubber, may be necessary. Rough clothing, which includes most material exclusive of cotton, may have to be discontinued, together with chafing, binding, or restricting garments.

The early management may require colloid baths, or soothing, bland, and antipruritic lotions. The skin should be lubricated

## COMMON DERMATOSES

A. J. AUST (1957)

Patients are instructed in the use of a loop blackhead extractor and advised to return to the clinic for management of stubborn comedones, frankly pustular lesions, cysts and coalescent areas.

It is our practice to fortify local therapy with cleansing by a naphtha or detergent soap once or twice daily to emulsify the oil and soften the keratin plug. This single procedure may be the most important local measure. We advise application of White Lotion N F IX at night which is removed in the morning. If this is inadequate, addition of a standard acne day lotion may help. The patient may prefer to use tinted proprietary preparations, many of which contain sulfur or resorcinol. Since seborrhea commonly is present, we advise the use of a 3 per cent resorcinol alcohol preparation of the scalp at bedtime. The scalp must be shampooed twice weekly.

The use of broad spectrum antibiotics to control the pustular phase has been observed to yield benefits that may be out of proportion to the apparent effect on the infection. The local use of soap containing hexachlorophene or lotions with neomycin bacitracin should be considered.

Acne is thought to be the result of physiologic hormonal changes, and the routine use of estrogens is inadvisable. Girls whose acne flares up prior to the menstrual period may profit by use of estrogens in the first half of the cycle. Thyroid extract is used only when clear cut evidence of hypothyroidism exists.

Natural sunlight is often beneficial if the atmosphere is not too hot and humid, although occasionally it may cause exacerbations. During the winter months the use of artificial ultraviolet light may be substituted.

The use of carbon dioxide slush or other peeling methods is best reserved for the dermatologist.

If the above measures do not control sebaceous activity, fractional doses of roentgen rays may be used over a period of 7 to 10 weeks.

Once the disease has been controlled, deep pits and protruberant scars may be smoothed somewhat by dermabrasion with a high speed rotary brush or bur.

Tropical acne, occupational acne, acneiform eruption due to drugs, acne with excoriations and acne rosacea do not fall within the scope of this discussion.

## ECZEMA

Acute and chronic dermatitis (eczema) constitutes over 25 per cent of our clinical dermatology. Much of the lack of uni-

local trauma, heredity, stress and fatigue, intestinal dysfunction, and sometimes of ingestion of fatty food, iodides, and bromides

The necessity of beginning therapy early cannot be emphasized too strongly, as psychic trauma, though often unsuspected, may be profound. Not only will the course of the disease be shortened, but the sequelae minimized. Characteristically, acne vulgaris subsides spontaneously at about 16 years of age. This fact should offer no deterrent to therapeutic effort, as the condition may persist for years or undergo recrudescence in tropical climates or at the menopause.

TABLE 1 *The 10 most common dermatoses in order of frequency as noted by various observers and as seen in this hospital*

Sulzberger and Baer <sup>3</sup> (Private practice)	Fox and Shields <sup>4</sup> (Private practice)	Gilman <sup>5</sup> (University students)	U S Naval Hospital Philadelphia Pa
Acne vulgaris	Acne vulgaris	Epidermophytosis	Acne vulgaris
Eczemas	Seborrhea	Acne vulgaris	Verrucas
Seborrhea	Epidermophytosis	Seborrhea	Chronic eczematous dermatoses
Epidermophytosis	Eczema	Verrucas	Epidermophytosis
Pruritus	Dermatitis venenata	Pyoderma	Pyoderma
Urticaria	Impetigo	Dermatitis venenata	Seborrhea
Atopic dermatitis	Scabies	Eczema	Atopic dermatitis
Drug eruptions	Urticaria	Pityriasis rosea	Nummular eczema
Psoriasis	Psoriasis	Moles	Pityriasis rosea
Lichen chronicus simplex	Pityriasis rosea	Herpes zoster	Psoriasis

The standard diet in military service usually affords ample amounts of the nutritious foods necessary in the management of the disease. If practicable, it is desirable to place the patient on a low fat, low iodine diet, which restricts intake of chocolate, cocoa, nuts, fried, fatty, greasy, or creamed foods, gravies, rich pastries or other desserts, shell fish, and iodized salt.

Since most service patients cannot select their diet, we avoid giving them lists of forbidden foods that might lead to undue caloric restriction. We do give them printed sheets explaining the nature of the disease and its treatment. It may be well to supplement the diet with vitamins, particularly A and D, in patients with keratinous follicles. A discussion of the diet affords an opportunity to correct many common misconceptions, to offer restrained reassurance, and to create an atmosphere of confidence by means of an optimistic, understanding attitude.

# THE COMMON DERMATOSES

DALE B WATKINS *Commander MC USA*

IT HAS BEEN observed that the 10 most common skin diseases represent approximately 75 per cent of all the dermatoses. The reports by Goodman<sup>1</sup> and Sohrweide<sup>2</sup> of statistical studies on more than a million dermatologic diagnoses showed that 6 diseases constituted about half of the total. Eight entities accounted for two thirds 1200 consecutive cases seen in the outpatient clinic of this hospital during the fall and winter of 1956. Although the numerical frequency of some dermatologic conditions has varied somewhat during the past 25 years according to the material available for study, changing diagnostic impressions, and other factors, our findings correlate extremely well as is shown in table 1.

This brief review will present the broader aspects of those dermatoses most commonly seen in military practice such as acne vulgaris, verruca vulgaris, epidermophytosis, and the eczemas. In the latter classification several entities are included that usually are discussed separately. The principles of management of the pyodermas are well known and will not be discussed in this article.

## ACNE VULGARIS

Acne vulgaris is observed so frequently in adolescents and in some older individuals as to excite little interest when seen in its milder forms. It occurs most often on the head, shoulders, and back, which are areas where sebaceous glands are numerous and where their activity is increased in nearly all cases. The first sign is commonly an area of inflammation about a keratinous comedo that has obstructed a sebaceous gland or hair follicle. When the force of the expanding comedo ruptures the wall of the follicle, sebum and keratin cause a foreign body reaction which often becomes infected. This may occur in oily skin in pre-adolescents, or at age 13 or 14 when papules and pustules commonly appear. These may become confluent or nodules and cysts may develop.

Variations in the course of acne may be a reflection of hormonal influences, secondary or focal bacterial infection,

(brand of papain) or of 0.13 gram of crystalline papain in 300 ml of a warm, aqueous solution of Zephiran Chloride (brand of benzalkonium chloride) was safe and effective when used as an enema.

**ACKNOWLEDGMENT** The authors wish to thank the following companies for providing the materials listed for use in this investigation: Lederle Laboratories Division, American Cyanamid Company, Pearl River, N. Y. for the Varidase, Enzyme 7 1162-A13; Enzyme 7 1162 A15 and Enzyme 7 1162 D11; Sharp and Dohme, West Point, Pa. for the pancreatic dornase; The Armour Laboratories, Armour and Company, Chicago, Ill. for the Tryptar and Chymar; The American Ferment Company, Incorporated, New York, N. Y. for the Caroid; Winthrop-Stearns, Incorporated, New York, N. Y. for the crystalline papain and crystalline chymopapain; and Wyeth, Incorporated, Philadelphia, Pa., for the Wadase.

#### MEETING OF MILITARY

#### OPHTHALMOLOGISTS AND OTOLARYNGOLOGISTS

The Society of Military Ophthalmologists and the Society of Military Otolaryngologists will hold their annual joint dinner meeting during the meeting of the American Academy of Ophthalmology and Otolaryngology in Chicago on 13 October. All members, on active duty or retired, are invited to attend. Reservations may be made at the time of registration for the Academy convention. Other information may be obtained from Major Stanley H. Bear, 3810th U. S. Air Force Hospital, Maxwell Air Force Base, Ala.

Caroid an impure type of papain has been reported to contain a number of enzymes. The proteolytic activities of papain have received most of the attention in the literature<sup>2</sup> however crude papain has been noted to have in addition a milk clotting factor<sup>3</sup> a lipase an amylase, and a lysozyme<sup>4</sup>. Crystalline papain contains a proteolytic enzyme and a milk clotting factor<sup>4</sup>. Crystalline chymopapain has a milk clotting factor equal in amount to that of crystalline papain but contains only half as much proteolytic enzyme as is found in crystalline papain<sup>7</sup>.

Clinical trials were made on 12 patients with impacted feces in whom enemas of water, mineral oil, or other substances had been used without success. The patients were given enemas of either 5.0 grams of Caroid or 0.13 gram of crystalline papain in 300 ml of a warm, aqueous solution of 1:5,000 Zephiran Chloride. In 10 of the 12 patients a bowel movement followed the retention of one of these enemas for 1 hour. In debilitated or weak patients the gluteal regions were brought together with strips of adhesive tape to prevent leakage of the fluid. In none of the patients was there clinical evidence of irritation of the rectum such as pain, tenesmus, tenderness, blood in the stools, or subsequent constipation or diarrhea. The following case reports are examples of the use of enemas containing an enzyme.

#### CASE REPORTS

**Case 1.** A 32-year-old white man with injury of the brain had a fecal impaction. Enemas of water followed by mineral oil which were given hourly for 5 hours were unsuccessful. A large hard stool was passed about one hour after the administration of an enema containing 5.0 grams of Caroid in 300 ml of a warm aqueous solution of Zephiran Chloride.

**Case 2.** A 66-year-old white man had an intestinal obstruction caused by a carcinoma of the descending colon. The ileocecal valve was not competent. A Miller Abbott tube was started. Two enemas of water and two of mineral oil were given without the passage of gas or feces. The administration of a fifth enema of 0.13 gram of crystalline papain in 300 ml of a warm aqueous solution of Zephiran Chloride resulted in the passage of a hard plug of feces measuring about 0.5 cm by 2.0 cm along with large amounts of flatus and liquid fecal material. The plug was soft at the periphery and it was assumed that the stool had occluded the narrowed lumen. The resultant decompression of the colon allowed time for passage of the Miller Abbott tube into the ileum and for restoration of the hemoglobin and electrolytes of the blood before a colostomy in the right part of the transverse colon was done.

#### SUMMARY

The results of the digestion of impacted feces by various enzymes have been reported. A solution of 5.0 grams of Caroid

paected variety (table 1) The solution of hydrogen peroxide exploded the fecal mass, but large quantities of gas were produced, and this could harm the patient Caroid (brand of papain), crystalline papain, crystalline chymopapain, Wydase (brand of hyaluronidase), and an aqueous solution of Zephiran Chloride (brand of benzalkonium chloride) were the only agents that softened or fragmented the feces in 24 hours The activity of the agents was in the order listed Combinations of the agents were made Caroid and Wydase in an aqueous solution of Zephiran Chloride, and crystalline papain and Wydase in an aqueous solution of Zephiran Chloride were superior, in that order, to other combinations, but the effect was only slightly increased by including Wydase in either combination

TABLE 1 Effectiveness in softening or fragmenting 2 gram portions of scybulous feces within 24 hours of adding various agents in 5 ml of solvent

Effective in order listed

Caroid (brand of papain) 1 0 gram in physiologic saline

Crystalline papain 0 13 gram in physiologic saline

Crystalline chymopapain 0 13 gram in physiologic saline

Wydase (brand of hyaluronidase), 150 turbidity reducing units in physiologic saline

Zephiran Chloride (brand of benzalkonium chloride) 1 1000 aqueous solution

Effective but with excessive production of gas

3 0 per cent hydrogen peroxide 2 5 ml in 2 5 ml of Phospho-Soda (brand of sodium biphosphate and phosphate)

Not effective

Water

Mineral oil

Glycerin

Varidase (brand of kinase and nuclease) streptokinase 100 000 units and streptodornase 25 000 units in physiologic saline

Lederle Enzyme 7-1162 A13 1 000 000 proteolytic units in physiologic saline

Lederle Enzyme 7 1162 A15 250,000 proteolytic units, in physiologic saline

Lederle Enzyme 7 1162 D11 1 250 000 proteolytic units, in physiologic saline

Pancreatic domase, 100 000 units, in physiologic saline

Trypsin (brand of trypsin) 0 25 gram in Sorenson's phosphate buffer solution

Chymar (brand of chymotrypsin) 0 1 gram, in physiologic saline

# TREATMENT OF IMPACTION OF FECES WITH AN ENEMA CONTAINING AN ENZYME

GEORGE C GODFREY M. D.  
JOSEPH W MILLER M. D.

**T**HE FECES may become hard and impacted in a patient who is extremely constipated or who refrains from having a bowel movement as long as possible because of a painful condition about the anus. The impaction may become so severe that the patient is not able to expel the feces or the attempt to do so is so painful that the effort is abandoned.

The treatment for an impaction of feces in the rectum has not changed materially through the years. The administration of a cathartic is valueless and may even be contraindicated in the face of an obstruction. Enemas of the soap-suds variety, retention enemas of warm olive oil, and enemas containing small amounts of hydrogen peroxide occasionally are beneficial. When enemas do not produce the desired result, the physician may introduce a well lubricated finger into the rectum and attempt to fracture the hard mass. This manipulation is followed by the administration of a soap-suds enema to clear the rectum of the broken stool. The digital manipulation is painful and disagreeable to the patient and when the impaction is large and stony, administration of an anesthetic may be necessary for removal of the mass.

Help may be obtained in solving this problem if thought is given to the composition of the feces. Feces normally are composed of food residues that are not digested or not absorbed, remains of intestinal and digestive secretions not destroyed or reabsorbed, substances excreted into the intestinal tract, notably phosphates and other salts of calcium, iron, and other metals, and bacterial flora of the intestinal tract with their metabolic end products and cellular elements.<sup>1</sup>

If partial or complete disintegration of the scybalous stool could be accomplished by an enzyme, the vehicle carrying the active agent could wash the fragments out of the rectum. With this concept in mind, 5 ml samples of solutions of various agents were applied to successive 2 gram portions of feces of the im-

physiological can be demonstrated by the improved performance of physical work after men have been forced to drink sufficient water to completely replace sweat losses.<sup>7, 15</sup>

The only known method of repairing the damage done to the human machine by dehydration is to replace lost body water. The signs and symptoms associated with simple dehydration disappear rapidly and dramatically when water is drunk.

cold diuresis is like water diuresis except that increased chloride excretion obtains in the former

Blood volume decreases after exposure to cold<sup>10</sup> The skin and subcutaneous tissues become dehydrated Frazier<sup>10</sup> maintains that the dehydration is a protective measure against freezing of the skin, for it is well established that dehydration of cells and tissues favors their survival when exposed to extreme cold<sup>11,12</sup> In general, cold depresses the water requirements of man However, when heavy arctic clothing is worn, sweating may occur when men are performing work which results in an energy production equivalent to about 175 calories per square meter of body surface area per hour

### SUMMARY AND CONCLUSIONS

From the review of the scientific data cited, one can derive certain principles concerning the water requirements of man

It is clearly evident that the intake of water needed by man varies under conditions of environment (temperature, humidity, sunlight), and of activity (rest, marching, load carrying)<sup>24</sup> No single table of water allowances can be set up which will apply in all situations The water balance system in man is regulated physiologically and no interpretation of facts justifies a belief that training or will power can change that balance, or keep the human machine in an effective functioning condition without the necessary elements Best evidence to date indicates that constipation is seriously harmed either by drinking sea water alone, or diluted with fresh water<sup>25</sup>

Table 2, which reflects the military point of view concerning water requirements of man, may be open to dangerous misinterpretation It should be emphasized that the table gives minimum requirements for men under temperate conditions temperature around 70°F and relative humidity 50 per cent or less Under no circumstances should this table be applied to men in the desert or tropics Under mild desert conditions, with minimum activity, 2 quarts of drinking water per man are needed each day As the ambient temperature rises or activity increases, the amount of water required by a man per day becomes greater When the temperature approaches 100°F and soldiers are engaged in strenuous maneuvers, more than 12 quarts of water per day per man may be needed to keep the troops in effective functioning condition

As men become acclimatized to heat their voluntary intake of water increases Ordinarily, however, this intake replaces only about one half of the water lost by sweat Thirst is not an adequate index of water requirement in the individual That dehydration resulting from sweat losses in the heat is truly

## MAN'S WATER NEEDS

August 1957)

to warrant the effort whole fish contains only enough water to regenerate the excretion of metabolized nitrogen from the protein in the fish. None of the water of the ingested fish is retained and the subject's own water loss is not impeded. Consequently when water supply is limited ingestion of protein foods is definitely undesirable. Carbohydrate is then the foodstuff of choice. Fat in the fish tested in these studies apparently did not influence the results.

During fasting the daily water requirement of a man who indulges in practically no physical activity is 700 ml. The addition of 100 grams of glucose to the diet could decrease the water requirement chiefly because of the sparing action of carbohydrate on protein. Table 3 illustrates this point. From the table it is evident that at least 100 ml of water for the cristaway may be replaced by 100 grams of glucose with no disturbance of water balance. Moreover the glucose itself contributes to the overall well being of the individual carrying

TABLE 3. Effect of glucose on water requirement of man

Condition	Urinary water excretion in ml	Available body water in ml
Fasting	521	518
Glucose 100 gram	23	360
Reduction	298	158
$G \text{ in in water exchange} = 98 \cdot 158 = 10 \text{ ml}$		

Studies of human volunteers on rafts in the Gulf of Mexico indicated an average daily evaporative loss of 730 ml of water. Assuming minimal exertion and negligible seasickness it is concluded that 500 to 1 000 ml of water will prevent dehydration in semifasting survivors on lifeboats or rafts on tropical seas.

## COLD CLIMATES

In arctic and subarctic areas the problem of adequate water intake by man is not as critical as in hot climates. In those regions the loss of water by sweat is not great and everywhere even on sea ice there are to be found sources of potable water.

Exposure to cold has a significant diuretic effect on man. It has been suggested that this effect is brought about by suppression of the activity of the posterior lobe of the pituitary. Intramuscular injections of Pitressin Tannate (brand of Vasopressin Tannate) inhibit the cold diuresis which stems from a decreased tubular reabsorption of water changes in renal hemodynamics need not be postulated. In many characteristics

tion of in  
inking

n airplane flying over the sea, are  
of water Sea water has such a high  
salts in solution as to render it harm

Proposals have been made that a limited supply of drinking water, on a life raft, could be extended by mixing it with sea water Such a procedure is deleterious, and will effectively shorten man's survival time<sup>22</sup> Hervey and McCance<sup>23</sup> have shown that 3 lines of evidence argue against the addition of sea water to an already limited water supply

1 Drinking of any significant amount of sea water accelerates the increase in the total osmotic pressure of the human body

2 An apparent improved water balance does occur initially after drinking sea water However, fluids are added only to the extracellular spaces and that occurs at the expense of intracellular water Since the latter is not an inexhaustible source, any apparent initial benefit must soon come to an end

3 Over any prolonged period, the apparent gain in water balance is replaced by an osmotic diuresis, which would be self-perpetuating

In view of these facts McCance and co-workers urged that no further credence be given to the unsafe suggestion that castaways drink sea water, even in small amounts added to fresh water rations<sup>23 24</sup> Results obtained by investigators in the United States<sup>25</sup> support this contention

August 1957)

per cent occur during the day these values vary from 30 to 70 per cent. Air movement is usually at a minimum. Under such conditions evaporation from lungs and skin is much reduced and in active men temperature control by sweating is impaired.

However, the total evaporative heat loss in men resting at 34°C and 15 to 75 per cent relative humidity is remarkably constant. In tropical atmospheres men sweat profusely and much unevaporated sweat drips from the skin and is lost insofar as evaporative cooling is concerned. The amount of sweat so wasted increases markedly as rate of work and metabolism increases.

In a hot dry atmosphere a working man may have to evaporate over 1 liter of sweat per hour to regulate his body temperature. Although in a tropical environment less will be lost under comparable conditions of activity even an inactive man in the tropics loses as much as 200 ml of sweat per hour. In order to maintain human efficiency, the water lost in sweat must be replaced by drinking.

Thirst is not an adequate index of the amount of fluid required, for man's thirst is quenched by drinking water long before sweat losses are replenished. Continuous maintenance of hydration by hourly replacement of loss is not wasteful of water; a dehydrated man sweats insignificantly less in the course of an hour's work than does a completely hydrated individual.

In a comparative study of sample tropical and desert environments it has been shown that the heat stress imposed in the Arizona desert is about 2 to 3 times greater than in the Florida tropics. In the desert area about twice the sweat was produced in a 24 hour period by men doing routine military duty as in the tropical zone. Fluid intake was similarly greater in the desert. Urinary volume was similar in each environment. Table 2 summarizes these results.

TABLE 2 Water exchange in man in the Arizona desert and the Florida tropics

Constituent	Desert	Tropics
Fluid intake 1/24 hr	590 ± 203	361 ± 09
Sweat loss 1/24 hr	495 ± 203	233 ± 123
Urinary output 1/24 hr	094 ± 066	097 ± 059

### SURVIVAL AT SEA

Persons who are forced to spend appreciable time on a life raft or in a life boat whether because of the sinking of a surface

## MILITARY DOCTRINE

The thinking of American military leaders on water requirements of man is expressed in various official manuals. The Corps of Engineers of the U S Army has, according to AR 115 20, 12 November 1952,<sup>\*</sup> primary responsibility for providing potable water to troops. TM 5 295, August 1956,<sup>\*</sup> provides the daily water requirements of man in combat, bivouac and in temporary camps (table 1). FM 31-25, Desert Operations states

TABLE 1 Daily water requirements<sup>\*</sup>

Unit consumer	Conditions of use	Gallons per unit consumed per day	Remarks
Man	In combat <i>Minimum</i>	1/2 1	For periods not exceeding 3 days, when operational rations are used
	Normal	2	When field rations are used
		3	Drinking plus small amount for cooking or personal hygiene
	March or bivouac	2	Minimum for all purposes
	Temporary camp	5	Desirable for all purposes (does not include bathing)
	Temporary camp with bathing facilities	15	

*\*Rate of Water Consumption* Trained troops operating in deserts need approximately 1 1/5 gallons of water per man per day. This ration is for drinking, cooking, washing, shaving, and brushing teeth. Since bathing on this ration is impossible, an occasional damp rubdown is substituted. The minimum water ration is three quarters of a gallon per man per day. After 3 days, however, in individual efficiency decreases on this reduced ration. In other countries, trained and conditioned men, traveling at night and finding shade during the day, can operate 5 days on a quart of water per man per day. This ration, however, seriously lowers combat efficiency.<sup>110</sup>

## ROLE OF WATER IN TEMPERATURE REGULATION

The normal body temperature of man is on the average about 37°C (98.6°F). Regulation of this temperature results from the balancing of 2 opposing forces: heat production versus heat loss. Heat is produced by the oxidation of fat, protein, and carbohydrate. Exercise, emotion, shivering, and the specific dynamic action of ingested foods all serve to increase oxidative heat production.

## MAN'S WATER NEEDS

August 1957

Heat is lost from the body by radiation convection and evaporation. In temperatures ranging from  $28^{\circ}\text{C}$  ( $83^{\circ}\text{F}$ ) downward a lightly clad man in the basal metabolic state dissipates 20 to 25 per cent of the total heat lost from evaporation of moisture through the lungs and skin. If the ambient temperature rises above that of the skin—about  $30$  to  $31^{\circ}\text{C}$  or  $85$  to  $87^{\circ}\text{F}$ —the sweat glands in the skin begin to function. This safety mechanism of sweating permits the loss of large amounts of heat from the body through evaporation of sweat from the surface of the skin.  $0.550$  kg calorie of heat is dissipated through the evaporation of  $1$  gram of water from the skin or lungs. Great muscular activity produces appreciable heat in the body and high ambient temperatures interfere with rapid dissipation of body heat. Large quantities of water in the form of sweat are required to dissipate the heat produced. As will be illustrated later in this article the amounts of water lost for brief periods may be as high as several liters per hour under some conditions although a loss of only  $1$  liter per hour can be maintained for a full day.

## DESERT

What is a desert? The outstanding characteristic of a desert is the continual lack of water sometimes accompanied by high mean temperatures, and desiccating winds. These factors acting together put a severe load on the cooling mechanism of the body.

Residence in the desert for any length of time results in an 8-fold or more increase in evaporative loss of water in man. During exercise in the desert rates of evaporation as high as  $1.6$  liters per hour and more have been found. As a consequence, water intake is increased 3 to 6 times. The daily water turnover by the body under these conditions may be as much as 10 to 30 times the daily variation in body weight. Under extremely torrid conditions a total volume of 10 liters of sweat in 24 hours may be produced. This amount of water thus lost must be replaced by drinking.

Studies made on soldiers stationed in Shaiba Iraq during World War II suggest that, when the daily maximum temperature is about  $115^{\circ}\text{F}$ , a daily water intake of approximately  $7\frac{1}{2}$  liters per day is needed to maintain body water balance. On the basis of this work it was recommended that each man should drink enough water to produce 30 oz of urine per day. A low urinary volume was taken as an early sign of collapse from water imbalance. A salt issue of 48 grams per day was recommended. It is common practice to have heavy construction workers drink 0.9 per cent sodium chloride solution when working in the heat.

A liberal intake of salt by persons living and working in desert climates is essential to well being, especially during

## MILITARY DOCTRINE

# WATER REQUIREMENTS OF MAN

CHARLES G WILBER Ph D

**T**HE CRADLE of life on this planet was water the most predominant substance in all living Certain physical characteristics of water make it uniquely important in biological processes Except for liquid ammonia water has the highest heat capacity of all liquids The large amount of water in all living things therefore prevents rapid changes in their body temperatures Water has the highest latent heat of evaporation of any substance known and this characteristic makes for body cooling through evaporation of sweat saliva and moisture in the air way<sup>1</sup>

Water the "universal solvent," with its low electrolytic dissociation, its high dielectric constant and the related high dissociation of inorganic substances dissolved in it is uniquely fitted for its role in living organisms<sup>2</sup> including homeothermal man who lives in an environment characterized by wide changes in temperature and moisture In order to maintain the human machine in efficient working condition the total amount of water in the body must be kept within narrow limits despite a large and variable daily turnover A discussion of the general biological significance of metabolic water is given by Babcock<sup>3</sup> It is an older work but contains much useful information

This article will summarize the water requirements of man under the various environmental conditions encountered in the process of living<sup>4</sup>

## AVERAGE WATER EXCHANGE IN MAN

A man of average build contains about 60 to 70 per cent by weight of water or a total of about 40 l<sup>4</sup> In such a man about 2.5 liters of water are lost each day by moisture in expired air by diffusion through the skin, by secretion of sweat and of urine and in the feces A like amount of water is taken in as fluid, as a component of food, and as a by product of the metabolism of foodstuffs Conditions of increased muscular activity or of high environmental temperatures will modify the average daily water turnover in a striking manner<sup>5</sup> Unlike fat and carbohydrate, which yield appreciable water upon oxidation, protein requires water for excretion of nitrogen containing end products, especially urea<sup>7</sup>

From U S Army Chemical Center Md

It will be noted that one patient (L M) had been receiving TP before this study of TCP was begun. This patient's response to TP, given on a demand basis, is recorded along with her response to TCP.

### SELECTION OF PATIENTS

It is generally agreed that the treatment of choice in carcinoma of the breast is initially surgery, then radiation therapy, and then hormone therapy.<sup>4</sup> We chose patients in whom we had exhausted the first two methods of treatment, or, as in the case of M S, those who refused these methods.

For the purpose of standardization of research aiming toward more valid comparisons, King's criteria in the selection of patients were used: "(1) a diagnosis of far advanced cancer of the breast with a variety of metastases, (2) all the surgical treatment practicable completed, (3) benefits possible from roentgen therapy exhausted, (4) establishment of a postmenopausal status, either natural or from irradiation or surgical castration brought about at least three\* months before start of use of testosterone, and (5) development of pain of cancer origin requiring narcotics for relief and/or disability requiring nursing care."<sup>5</sup>

The course of the patients was followed regarding pain, activity, and morale. In recording and graphing the courses, the four levels of each used by King were followed. *Pain* (1) no pain—or so mild that no medication was necessary, (2) mild pain—requiring aspirin or its equivalent, (3) moderate pain—requiring codeine, and (4) severe pain—requiring Demerol Hydrochloride (brand of meperidine hydrochloride) or other opiates. *Activity* (1) full activity, (2) self service, (3) bed and chair with bathroom privileges and some walking, and (4) confined to bed. *Morale* (1) excellent, (2) good, (3) fair, and (4) poor. Believing that relief of symptoms should be as complete as possible, we were quite liberal in our use of narcotics.

Figure 1 gives the graphic profile of the above named symptoms and signs for each of the 12 patients, all of whom lived over 30 days after the beginning of testosterone therapy. Figure 2 shows the life span in years after pathologic discovery with indication of the time after discovery that the ovaries were functioning, and the duration of testosterone administration. All additional therapy is inserted in symbols.

### SIDE EFFECTS OF TREATMENT

The most annoying and constant side effect was hoarsening and deepening of the voice, occurring in 5 patients in impor

# WATER REQUIREMENTS OF MAN

CHARLES G. WILBER, Ph.D.

**T**HE CRADLE of life on this planet was water, the most predominant substance in all living. Certain physical characteristics of water make it uniquely important in biological processes. Except for liquid ammonia, water has the highest heat capacity of all liquids. The large amount of water in all living things therefore prevents rapid changes in their body temperatures. Water has the highest latent heat of evaporation of any substance known, and this characteristic makes for body cooling through evaporation of sweat, saliva, and moisture in the air way.<sup>1</sup>

Water, the "universal solvent" with its low electrolytic dissociation, its high dielectric constant, and the related high dissociation of inorganic substances dissolved in it, is uniquely fitted for its role in living organisms,<sup>2</sup> including homeothermal man, who lives in an environment characterized by wide changes in temperature and moisture. In order to maintain the human machine in efficient working condition, the total amount of water in the body must be kept within narrow limits despite a large and variable daily turnover. A discussion of the general biological significance of metabolic water is given by Babcock.<sup>3</sup> It is an older work but contains much useful information.

This article will summarize the water requirements of man under the various environmental conditions encountered in the process of living.<sup>4</sup>

## AVERAGE WATER EXCHANGE IN MAN

A man of average build contains about 60 to 70 per cent by weight of water or a total of about 49 l. In such a man about 2.5 liters of water are lost each day by moisture in expired air, by diffusion through the skin, by secretion of sweat, and of urine, and in the feces. A like amount of water is taken in as fluid, as a component of food, and as a by-product of the metabolism of foodstuffs. Conditions of increased muscular activity or of high environmental temperatures will modify the average daily water turnover in a striking manner.<sup>5, 6</sup> Unlike fat and carbohydrate, which yield appreciable water upon oxidation, protein requires water for excretion of nitrogen-containing end products, especially urea.<sup>7</sup>

From U. S. Army Chemical Center, Md.

Figure 1 Patients clinical courses after start of testosterone therapy

tance to the patients and in frequency was hirsutism, 3 patients having an increase in hair of the upper lip, 3 of the chin, 1 of the chest, and 1 of the extremities. One patient noted a general loss of hair (thinning) but no patient noted temporal recession or pubic peaking. One patient noted increased stiffness of her joints in general, 1 increased libido, 2, acne 2, nervousness 2, generalized edema, 1, wheezing and choking with subjective swelling of the neck, and 1, tingling in the feet and fingers.

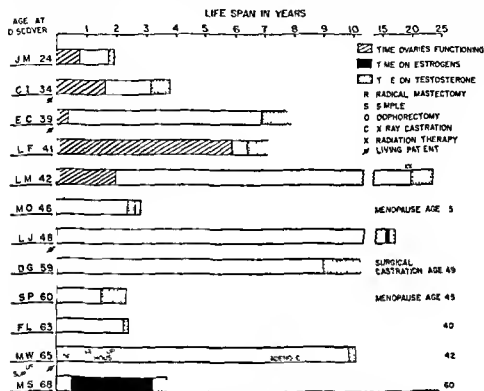

Figure 2. Life span in years of patients after discovery of carcinoma

Temporary side effects were increased stiffness of joints in 2, increased lameness in 3, increased pain in 3, increased weakness in 1, and decreased ambition in 1 patient. No patient was aware of an increase in the size of the lesions, and one noted a temporary decrease after her first injection.

One patient believed that she had a temporary decrease in hearing after her first injection. She said people sounded far away for about two hours the day after the injection, along with twinges of pain and slight aching in her ears.

Hypertrophy and irritability of the clitoris, dysuria and vaginal discharge were observed in King's patients but these side effects were not observed in the present series. Nausea and

vomiting were more prominent in his patients, and one of his patients developed a goiter. Side effects, pleural effusion and dyspnea, noted by King have apparently been eliminated by the use of a low salt diet.

Not all patients were bothered by the side effects, and some manifested none whatsoever. Along with the benefits of therapy, the appetite and weight (without edema) increased. It is noteworthy that only one patient thought that the side effects were troublesome enough to discontinue treatment. She had been noted to be emotionally unstable for years and was thought by some physicians to be psychoneurotic.

Table 1 compares the findings of this study with those of King.

TABLE 1 *Comparison of the findings of this study with those of King<sup>1</sup>*

	King's series	Present series

Survival time of 8 patients who have died

Survival time of total group of 12 patients

First two injections only

### SUMMARY AND CONCLUSIONS

Twelve patients with terminal breast cancer treated with Depo Testosterone Cyclopentylpropionate (brand of testosterone cyclopentylpropionate (TCP)) have been observed and the results compared with those of a similar series treated with testosterone propionate (TP).<sup>2</sup>

No way was revealed in which the response of a patient might be predicted. The results were so far from uniform in the time of survival after the start of testosterone therapy that average values tend to lose some of their meaning.

The responses were all favorable, all patients surviving over 30 days after the start of testosterone therapy. Only one patient found the side effects worse than slightly annoying.

King<sup>3</sup> described a correlation between survival time on testosterone therapy and the presence or absence of a temporary increase in severity of symptoms. This series did not confirm King's observation. As in his series, relief of bone pain was the greatest effect of therapy, and activity and morale varied inversely with the level of pain in most cases. Appetite, weight and strength also followed closely.

The patients with bone metastases did much better in general than those with predominantly intrathoracic and/or cerebral metastases. The survivals of the latter group after start of testosterone therapy were 36, 43, 69, and 312 days and thus 3 of the 4 were much lower than the average of all 12 patients.

Little or no cyclic disturbance was noted under this program of 500 mg. TCP per month. The frequency of side effects was also less than that noted by King.

On the basis of the comparison of these two somewhat limited studies we conclude that:

- 1 Testosterone has a definite place in the palliative therapy of carcinoma of the breast after operative and radiation therapy have been given adequate trials.

- 2 TCP as used herein compares favorably with TP as used by King in (a) effectiveness in relief of bone pain maintaining activity at high levels, maintaining morale at high levels and prolonging life and increasing the patient's usefulness, (b) undesirable side effects, (c) dangers and toxicity, and (d) ease and convenience for the patient and the doctor in frequency of injections and amount needed.

- 3 TCI appears to be the drug of choice over TP in the palliative androgen therapy of advanced carcinoma of the breast and deserves further clinical evaluation.

---

ACKNOWLEDGMENT The author wishes to express his appreciation to Dr. Mark A. Hayes for guidance and for use of the Yale Tumor Clinic facilities in this investigation.

# SENSITIVITY OF MALE RANA PIPIENS TO THE SPERMATOZOA RELEASING PRINCIPLE OF HUMAN PREGNANCY URINE

MORRIS D SCHNEIDER Major MC USA

MELVIN A FACKLER

ROLAND S ARONSON Colonel MC USA

**R**ELASE of spermatozoa from the testes of hibernating amphibia may be induced by injections of either crude extracts of anterior pituitary or the urine of a pregnant woman<sup>1-4</sup>. A kaolin adsorption technic or some variation of it has been applied to urine to concentrate the gonadotropin of pregnancy<sup>5-10</sup>. The concentrates contain chemically complex impurities, and information about them and the role they play in the male frog test for pregnancy is sparse. Recent evidence suggests that a luteinizing hormone (LH) and an LH like substance contained in human chorionic gonadotropin (HCG) are concerned in the release of spermatozoa from male *Rana pipiens*<sup>11</sup>.

The present investigation has been restricted to studies of the biological activity and certain other properties of concentrates of the urinas of pregnant women attained by a modified kaolin adsorption technic. The studies reported are as follows: (1) a comparison of the responses of male *Rana pipiens* and immature female white mice to spermatozoa releasing principle and ovarian hemorrhagic follicle inducing substance; (2) the qualitative identification of certain organic materials present in the prepared concentrate of human pregnancy urine, and (3) a limited investigation of the stability of the spermatozoa releasing principle contained in the concentrate. The preparations were bioassayed semiquantitatively. The results reaffirm the sensitivity and reliability of the male *Rana pipiens* test as an effective, practical, and rapid procedure for supplementing the clinical diagnosis of pregnancy.

The modified kaolin adsorption technic for concentrating urinary chorionic gonadotropin has been used in several thousand routine qualitative tests during the past two years. In an

arbitrarily selected group of patients, positive tests were obtained on 93 per cent of those who later proved to be pregnant. No false positive tests were reported.

### METHODS AND MATERIALS

**Preparation of Crude Concentrate** The unpreserved urines of pregnant women who had experienced from 50 to 80 days of amenorrhea, constituted the starting material. The kaolin adsorption techniques of Scott<sup>9</sup> and Dekanski<sup>10</sup> were applied in the following manner. 3 to 5 drops of an alcoholic solution containing 1 per cent bromeresol green and 3 per cent phenolphthalein were added to a liter of urine. The urine was acidified with 5 to 10 ml of 20 per cent hydrochloride to about pH 4, as indicated by a yellow end point. Fifty milliliters of a 20 per cent aqueous suspension of kaolin was added, the mixture shaken, and the adsorbate permitted to settle out for about 1 hour.

The supernatant liquid was decanted and the kaolin centrifuged for 3 minutes at 1,000 to 1,500 r p m. About 2 ml of normal sodium hydroxide solution was added to the lightly packed kaolin adsorbate. A purple aqueous phase was separated by centrifugation for 10 minutes at 3,500 r p m and decanted into a clean test tube. Five per cent hydrochloride was introduced drop by drop until the aqueous phase showed an intense green or blue green end point (pH 6 to 6.5). Coincident with this color change, there usually formed a massive, flaky blue green precipitate.

The aqueous suspension was diluted to 2 per cent of the volume of the starting urine. Fiftyfold concentrates, prepared from 100 to 120 ml of urine, were used routinely in qualitative frog tests.

**Purified Urinary Gonadotropin** The crude suspension was centrifuged at low speed and the aqueous phase separated. This was shaken with two volumes of cold acetone and the mixture held at 0°C for 2 hours. A brownish precipitate formed and after one washing in acetone was redissolved in distilled water to 2 per cent of the starting volume of the urine. The aqueous extract was shaken with one fourth volume of chloroform, centrifuged at low speed, and refrigerated. The spermatozoa releasing substance was contained in the aqueous phase. The insoluble residue derived from the crude suspension was resuspended in water to 0.5 per cent of the original volume of the urine.

**Bioassay of Concentrates** *Rana pipiens* Preparations were assayed for spermatozoa releasing activity by a semiquantitative technique. An arbitrary scale was adopted for measuring the intensity of the response, similar to that reported by Burgos and

arbitrarily selected group of patients, positive tests were obtained on 93 per cent of those who later proved to be pregnant. No false positive tests were reported.

### METHODS AND MATERIALS

**Preparation of Crude Concentrate** The unpreserved urines of pregnant women who had experienced from 50 to 80 days of amenorrhea, constituted the starting material. The kaolin adsorption techniques of Scott<sup>9</sup> and Dekaaski<sup>10</sup> were applied in the following manner: 3 to 5 drops of an alcoholic solution containing 1 per cent bromeresol green and 3 per cent phenolphthalein were added to a liter of urine. The urine was acidified with 5 to 10 ml of 20 per cent hydrochloride to about pH 4, as indicated by a yellow end point. Fifty milliliters of a 20 per cent aqueous suspension of kaolin was added, the mixture shaken, and the adsorbate permitted to settle out for about 1 hour.

The supernatant liquid was decanted and the kaolin centrifuged for 3 minutes at 1,000 to 1,500 r p m. About 2 ml of normal sodium hydroxide solution was added to the lightly packed kaolin adsorbate. A purple aqueous phase was separated by centrifugation for 10 minutes at 3,500 r p m and decanted into a clean test tube. Five per cent hydrochloride was introduced drop by drop until the aqueous phase showed an intense green or blue green end point (pH 6 to 6.5). Coincident with this color change, there usually formed a massive, flaky blue green precipitate.

The aqueous suspension was diluted to 2 per cent of the volume of the starting urine. Fiftyfold concentrates, prepared from 100 to 120 ml of urine, were used routinely in qualitative frog tests.

**Purified Urinary Gonadotropin** The crude suspension was centrifuged at low speed and the aqueous phase separated. This was shaken with two volumes of cold acetone and the mixture held at 0°C for 2 hours. A brownish precipitate formed and after one washing in acetone was redissolved in distilled water to 2 per cent of the starting volume of the urine. The aqueous extract was shaken with one fourth volume of chloroform, centrifuged at low speed, and refrigerated. The spermatozoa releasing substance was contained in the aqueous phase. The insoluble residue derived from the crude suspension was resuspended in water to 0.5 per cent of the original volume of the urine.

**Bio assay of Concentrates** *Rana pipiens* Preparations were assayed for spermatozoa releasing activity by a semiquantitative technique. An arbitrary scale was adopted for measuring the intensity of the response, similar to that reported by Burgos and

Ladman<sup>11</sup> The crude concentrates of the urines of pregnant women were diluted in saline solution or distilled water so that each inoculum of 2 ml contained total solids ranging from 3.5 to 70 mg. Injections were made into the dorsal lymph sacs of normal healthy male frogs. Cloacal contents were expelled into test tubes and examined microscopically for spermatozoa. *Immature female mice* White mice under 21 days of age were used. Each dilution of the urinary preparations tested contained a different amount of total solids. Five injections of 0.2 ml each were made subcutaneously, at 3 to 4 hour intervals on 2 consecutive days. Mice were sacrificed 72 hours after the first injection. The ovaries and uterus were excised and examined under a dissecting microscope for hemorrhagic follicle end points, and total wet weight was determined with a sensitive balance.

**Spectroscopic Measurements** Partially purified aqueous concentrates were examined spectroscopically in the ultraviolet region. A powerful ultraviolet absorbing compound was present in the preparations. It was necessary to dilute each extract 1:50 in distilled water in order to obtain the spectral measurements. The compound exhibited a sharp extinction maximum at 288 to 290 m $\mu$  which was indistinguishable from that observed in a reference solution of uric acid. Colored derivatives of crude and purified aqueous concentrates were obtained by reaction with sulfuric acid-sulfhydryl reagent (BCyT), according to a method of Dische.<sup>12</sup> Readings were made in a Beckman Model DU Spectrophotometer.

## RESULTS

**Semiquantitative Assays** Yields of crude and purified concentrates after drying to constant weight, were approximately 700 and 165 mg respectively per liter of urine. Bioassays of the latter preparations in frogs indicated that there were 150 to 200 effective doses of reactive substance per liter of urine. The toxicity of the concentrates for frogs was low. Intense stimulation of release of spermatozoa was achieved with about 7 to 10 mg of crude concentrate. Intense responses frequently were accompanied by the appearance of "rosettes" described by Burgos and Ladman<sup>11</sup> as numerous spermatozoa clustered about Sertoli cells. Data of assays are summarized in table 1. The stability of an aqueous preparation is illustrated in table 2. Comparative assays of crude and purified preparations in *Rana pipiens* and in mice are shown in table 3. Partly purified aqueous preparations contained uric acid and a carbohydrate component (fig. 1).

## DISCUSSION

Concentrates of urine prepared by kaolin adsorption technique contain organic constituents among which are powerful ultra

violet light absorbing nucleic acid, uric acid, and carbohydrate substances. The nucleic and uric acids appear not to be participants in the spermatozoa releasing action in *Rana pipiens*. Prep

arations that contain the spermatozoa releasing principle are relatively rich in a saccharide material, the colored derivative of which in sulfuric acid and in the presence of cysteine absorbs strongly in the 404 to 408 m $\mu$  region. The significance of the sac

charide is not known, however the information derived from this study affords no basis for suspecting that more than one organic compound is responsible for expulsion of spermatozoa from the testes of *Rana pipiens* and for inducing the ovarian hemorrhagic follicle end point of the immature female mouse. Under the conditions of our experiments similar end points in male frogs and in immature female mice were obtained with the same preparations of human pregnancy urine.

4 Preparation dialyzed for 10 days at 5°C against distilled water

5 Preparation heated at 57-58°C for 30 minutes

In the performance of routine diagnostic tests questions arise as to the stability of the spermatozoa-releasing principle. This study has disclosed that the concentrates reported herein possess good stability and that the gonadotropin principle present in them is relatively resistant to heat, acid, alkali, acetone, and chloroform. Active particles may have undergone fragmentation, inasmuch as dialyzed preparations show about 50 per cent of the activity of the original concentrate. Unpreserved but refrigerated crude concentrates have retained their spermatozoa-releasing activity for 60 days. Partly purified aqueous concentrates preserved with chloroform have retained their activity for 190 days. It has been found practicable to prepare concentrates of urine and store them under refrigeration while awaiting supplies of frogs. Simultaneous qualitative tests with 10 or more specimens can be accomplished rapidly and economically.

### HELMINTHIC DISEASES IN THE UNITED STATES

"Trichinosis exemplifies the importance of helminthic diseases in this country the number of cases of trichinosis in the United States exceeds that in any other country in the world Tropical diseases are brought to the United States by people returning or migrating from other countries an example is American trypanosomiasis the first case of which in the United States was reported in Texas in 1955 *Schistosoma mansoni* and *Wuchereria bancrofti* are being brought to the mainland of the United States from the West Indies especially from Puerto Rico Many cases of schistosomiasis have been reported since 1950 especially in northern cities such as New York and Chicago Parasites endemic in one area within the United States are carried occasionally into other areas as is illustrated by an outbreak of infestation with *Strongyloides* in a school in Illinois after the arrival of children from New Mexico Two million American tourists have visited foreign countries since World War II Increased attention to the principles of sanitation and hygiene is urgently needed in order to reduce the disability now caused by parasites and to prevent parasites from establishing themselves in new areas "

p 121 May 11 1957

cordial leads. No abnormality of the QRS complex was noted.

The patient's course in the hospital was progressively rapidly downhill. She complained continuously of chest pain and a moderate cough. She was frequently given supplemental oxygen throughout her hospital stay. On 4 May it was decided to administer streptomycin sulfate and penicillin parenterally. She remained afebrile and her pulse rate was constantly recorded to be between 100 and 110. Her blood pressure continued at 110/70 mm Hg, and her respirations rose gradually to 15 per minute. On 7 May three attempts at thoracentesis were unsuccessful. She became anorectic, her respirations became shallow and she died quietly at 1215 on 7 May.

### DISCUSSION

Dr. Soderstrom: This case deals with an elderly woman who had enjoyed good health until the age of 70, except for the fact that she had had pleurisy of unknown cause at the age of 30 and a nervous breakdown at the age of 56. She died of a progressive illness 6 months after the onset of cough 3 weeks subsequent to the onset of chest pain and 7 weeks following the onset of dyspnea. Cough was intermittently productive of thick mucous material. Chest pain on the left side was at first intermittent and pleuritic in nature, later persistent and associated with localized tenderness over the chest wall. Dyspnea was without orthopnea until 1 day prior to death. It is possible that weight loss beginning 3 years prior to death marked the true onset of the patient's illness.

Objective findings were those of respiratory distress without cyanosis or clubbing of the fingers, left-sided pleural effusion and right-sided pulmonary congestion. Associated findings were tachycardia, hypertension, an aortic systolic murmur, arteriosclerosis of the abdominal aorta and kyphosis of the dorsal spine. The findings of an enlarged heart and of a mass in the right flank are questionable since they were based on a small examination of the abdomen. The electrocardiographic findings were not helpful. Laboratory findings were conspicuously unhelpful. There was no anemia, no leukocytosis and the

**Physical Examination** Physical examination revealed an emaciated senile white female who was alert rational and complained of pain in the left side of the chest. She was lying on her right side with her head slightly elevated and breathing noisily with considerable effort. She was 62 inches tall and weighed 100 pounds. Per temperature was 98.6°F, pulse rate, 100 and blood pressure 220/110 mm Hg. Examination of the chest demonstrated increased tactile fremitus on the right side and dullness of the left side of the chest from the 4th intercostal space downward posteriorly with localized tenderness over the left 5th and 6th intercostal spaces. Auscultation revealed decreased breath sounds over the area of the left lung and absent breath sounds over the left lower lung. Fine crepitant rales were present over the right upper lung. The cardiac rhythm was regular at 100 per minute and occasional extrasystoles were noted. A grade 2 blowing systolic murmur was heard at the base of the heart radiating to the neck and downward to the apical region. The liver edge was palpable 4 fingers breadth below the right costal margin in the midclavicular line and was tender to palpation. A moderately tender, palpable mass was noted in the right flank and was thought to be kidney. The bowel sounds were hyperactive. Pulses were prominent in all extremities. The skin was dry and wrinkled.

**Laboratory Findings** Hemoglobin was 15.5 grams per 100 ml, hematocrit 45 ml per 100 ml, sedimentation rate 18 mm, white blood cell count, 7900 per  $\mu$ l with a differential of 82 per cent neutrophils, 14 per cent lymphocytes, 2 per cent monocytes, 1 per cent eosinophils, and 1 per cent basophils. A serologic test for syphilis was negative. No urinalysis results were recorded. A roentgenogram of the chest showed extensive arteriosclerotic calcification in the aorta with marked elongation and tortuosity. The heart did not appear enlarged. In the right lung field there was marked pulmonary congestion and vascular prominence in and about the hilum tapering toward the periphery. The left lung was obscured by a large amount of pleural fluid. In the midthorax this fluid extended to about the level of the 10th rib and showed a lateral upward sweep occupying almost one half of the thorax at its midhorizontal level. A roentgenogram of the abdomen revealed nothing unusual except marked arteriosclerosis of the abdominal aorta. A smear of the sputum disclosed no acid fast organisms.

**Course in Hospital** The patient was placed in isolation because of the possibility of tuberculosis. She was given a low salt diet and oxygen by the nasal route continuously. Her digitoxin dosage was increased and a mercurial diuretic was given. The chest pain and restlessness required morphine every four hours for relief.

An electrocardiogram revealed depressed S-T segments in standard leads I, II, aVL and aVF and in all the lateral pre

viously sensitized pleural membrane. Therefore, tuberculous effusions occur most frequently 3 to 6 months after the primary infection. In the later stages of the disease effusions are less common probably because of pleural symphysis with obliteration of the pleural space.<sup>4</sup> Our patient's cough started some six months before discovery of pleural effusion, but it would seem extremely unlikely to me that a person would contract primary tuberculosis at such a late age. Rupture of an old tuberculous lesion with seeding of bacilli onto the pleural membrane is of course, possible, but we would expect to see some evidence of previous tuberculosis on the chest film. The sputum smear though of little true aid, might possibly have been positive were this tuberculous with such productive sputum. In military tuberculosis abundant effusions do not occur and her chest film does not resemble military involvement.

The acute bacterial, fungal, viral and rickettsial pneumonias can be readily excluded. With this much involvement some clinical or laboratory evidence of an acute infection should be present. It is only when the acute phases of the pneumonias are suppressed by inadequate antibiotic therapy that sterile empyemas develop which are difficult to interpret. Aspiration pneumonia, of course, is a possibility but it would not explain the patient's pain unless a lung abscess with rupture, empyema and cellulitis of the chest wall had occurred. One would expect such an abscess on the right rather than on the left side, purulent rather than mucoid sputum, and there should be some evidence of a systemic reaction. Much on the same basis we can exclude a pulmonary abscess secondary to pulmonary infarction, especially since we find no obvious source of peripheral emboli or evidence of rheumatic heart disease. The absence of an electrocardiographic pattern of right heart strain is also helpful. Nevertheless, a simple pulmonary abscess with involvement of the pleura remains a possibility. There is nothing in particular that favors this diagnosis but it must be considered since such abscesses can occur without any known provocation.

It seems very unlikely that this patient had chronic pulmonary suppurative disease such as bronchiectasis or cystic disease of the lung with the first development of symptoms at the age of 76 and without evidence of polycythemia, clubbing, or cor pulmonale. A much more likely possibility than inflammatory disease is I think an intrathoracic tumor. An aneurysm of the transverse arch usually enlarges to the left and presses on the trachea, esophagus and the left main stem bronchus. It can produce atelectasis with abscess and empyema or may lead to pleural effusion. However the patient's serologic tests were negative, the peripheral pulses were equal and there was no hoarseness or dysphagia. I think that the absence of paratracheal adenopathy is as good evidence against the lymphomas and sarcoidosis as is the patient's age. This more or less narrows the possibilities down to malignant lesions of the lung with involvement of the pleura or vice versa.

Primary malignant tumors of the pleura are extremely rare and tumors reported as derived from the pleura are regarded by some pathologists

1. The pleural rather than fluid or the pleura was very thickened and  
4. The lateral up-sweep seen on the chest film is most typical  
of pleural effusion. This characteristic curve is due to the fact that  
laterally the mass of fluid tapers upward to a thin edge.

Two reliable findings stand out: (1) a massive pleural effusion and (2) the subjective complaint of severe chest pain. Approaching the differential diagnosis from this standpoint, the first possibility is that of a hydrothorax due to congestive failure. The patient had hypertension, arteriosclerosis, and a calcified aortic valve. She had kyphosis of the dorsal spine and right ventricular hypertrophy has been reported secondary to kyphoscoliosis even in the absence of intrinsic cardiac disease.<sup>1</sup> She received digitalis and diuretics and this might explain why the hepatomegaly noted on physical examination was not apparent on a flat plate of the abdomen.

Against congestive failure as the primary cause of this patient's pleural effusion are the lack of peripheral edema, the location of the effusion, and the presence of chest pain with localized tenderness over the 5th and 6th intercostal spaces. In the majority of cases of pleural effusion due to congestive heart failure there is a predominance of fluid in the right pleural cavity. When bilateral, the amount of fluid is usually greater on the right. Why this occurs has been cause of much discussion in the literature. If pressure on the pulmonary veins is of significance, the dilated right auricular appendix may be the key to the problem. Most likely multiple factors are involved. An important factor may be the tendency of patients in congestive failure to lie on the right side.<sup>2</sup> Our patient did elect to lie on the right side yet her effusion was in the left pleural cavity.

Another significant finding against congestive failure with hydrothorax is the presence of pain. Chest pain secondary to hydrothorax is very unusual and occurs only if the mediastinal structures are displaced and put under stretch. Such pain is never associated with localized tenderness. On the basis of the above evidence I will exclude congestive failure. Hydrothorax secondary to renal disease, Laennec's cirrhosis, subdiaphragmatic lesions, or a Meigs' syndrome are mentioned only for completeness; there is nothing to favor any of these diseases.

At this point in the discussion it seems appropriate to consider inflammatory pulmonary diseases, and our primary concern among these is pulmonary tuberculosis. An acid fast infection is a distinct diagnostic possibility in this patient. At the age of 36-40 years prior to the onset of her terminal illness, the patient had pleurisy of unknown cause. We do not know whether this pleurisy was associated with effusion, nor do we know the patient's sensitivity to tuberculin. Recent experience indicates that although active tuberculosis does not follow dry pleurisy as often as was once thought, most cases of so-called idiopathic serous effusions are in fact tuberculous. Rich<sup>3</sup> has demonstrated that tuberculous pleural effusions have their source in the rupture of a tuberculous lesion, usually a lymph node, onto a pre-

viously sensitized pleural membrane. Therefore, tuberculous effusions occur most frequently 3 to 6 months after the primary infection. In the later stages of the disease effusions are less common, probably because of pleural symphysis with obliteration of the pleural space.<sup>4</sup> Our patient's cough started some six months before discovery of pleural effusion, but it would seem extremely unlikely to me that a person would contract primary tuberculosis at such a late age. Rupture of an old tuberculous lesion with seeding of bacilli onto the pleural membrane is of course, possible but we would expect to see some evidence of previous tuberculosis on the chest film. The sputum smear, though of little true aid might possibly have been positive were this tuberculous with such productive sputum. In military tuberculosis abundant effusions do not occur and her chest film does not resemble military involvement.

The acute bacterial, fungal viral, and rickettsial pneumonias can be readily excluded. With this much involvement some clinical or laboratory evidence of an acute infection should be present. It is only when the acute phases of the pneumonias are suppressed by inadequate antibiotic therapy that sterile empyemas develop which are difficult to interpret. Aspiration pneumonitis, of course, is a possibility, but it would not explain the patient's pain unless a lung abscess with rupture, empyema, and cellulitis of the chest wall had occurred. One would expect such an abscess on the right rather than on the left side, purulent rather than mucoid sputum, and there should be some evidence of a systemic reaction. Much on the same basis we can exclude a pulmonary abscess secondary to pulmonary infarction, especially since we find no obvious source of peripheral emboli or evidence of rheumatic heart disease. The absence of an electrocardiographic pattern of right heart strain is also helpful. Nevertheless, a simple pulmonary abscess with involvement of the pleura remains a possibility. There is nothing in particular that favors this diagnosis but it must be considered since such abscesses can occur without any known provocation.

It seems very unlikely that this patient had chronic pulmonary suppurative disease such as bronchiectasis or cystic disease of the lung with the first development of symptoms at the age of 76 and without evidence of polycythemia, clubbing, or cor pulmonale. A much more likely possibility than inflammatory disease is, I think, an intrathoracic tumor. An aneurysm of the transverse arch usually enlarges to the left and presses on the trachea, esophagus, and the left main stem bronchus. It can produce atelectasis with abscess and empyema or may lead to pleural effusion. However, the patient's serologic tests were negative, the peripheral pulses were equal and there was no hoarseness or dysphagia. I think that the absence of paratracheal adenopathy is as good evidence against the lymphomas and sarcoidosis as is the patient's age. This more or less narrows the possibilities down to malignant lesions of the lung with involvement of the pleura or vice versa.

Primary malignant tumors of the pleura are extremely rare, and tumors reported as derived from the pleura are regarded by some pathologists

as of pulmonary origin Doubt<sup>1</sup> reported five cases of primary pleural epithelioma among over 500 000 admissions to the Henry Ford Hospital Sarcomas of the diaphragmatic structures are even rarer Statistically therefore the chances for pulmonary carcinoma are infinitely better Could this patient have had a metastatic pulmonary lesion? In a female metastases usually reach the lungs from primary malignant tumors in the thyroid breast gastro-intestinal tract or kidney Chorioepitheliomas can also metastasize to the lungs The right kidney was palpated in this patient at the time of the initial physical examination but no mass was seen in the right flank on a roentgenogram There is nothing in the protocol to implicate the other organs that commonly are sites of malignancies with pulmonary metastases although admittedly the patient's stay in the hospital was too short for adequate screening Primary carcinoma of the lungs therefore should be placed at the top of the list in the differential diagnosis It can mimic any other pulmonary disease It explains this patient's course symptoms and findings better than any other entity Pleural and later chest wall involvement explains why the patient's pain which at first was pleuritic persisted after the development of pleural effusion and became associated with local tenderness Chest wall involvement also explains why the patient sought relief by lying on the right side Pulmonary carcinoma fits the patient's age group better than does tuberculosis which admittedly cannot be definitely excluded

#### Dr Sode's diagnoses

- 1 Primary carcinoma of the lung, peripheral type, with involvement of the pleura and the anterior chest wall possibly with involvement of the 5th and 6th ribs on the left side
- 2 Arteriosclerosis with calcification of the abdominal aorta and calcified aortic valve

#### PATHOLOGIC FINDINGS

D Ervonian Dr Sode gave an excellent analysis of the case and as we shall see reached the correct diagnosis

At the time of autopsy the body was that of an emaciated elderly white female appearing to be about 80 years of age There were no unusual features except those associated with her advanced age When the pleural cavities were opened about 3 000 ml of straw colored fluid was removed from the left pleural cavity The entire pleural surface of the left side was studded with myriads of small firm gray nodules measuring up to 4 mm in diameter Similar but fewer nodules were present on the pleura of the right side Within the pericardium there was about 200 ml of straw colored fluid and the entire left side of the pericardial sac was thickened fibrotic and firmly adherent to the visceral pleura of the left lung

The left lower lobe

- 2 Arteriosclerosis with calcification of the abdominal aorta and calcified aortic valve

#### PATHOLOGIC FINDINGS

Dr Ervan on Dr Sode gave an excellent analysis of the case and as we shall see reached the correct diagnosis

At the time of autopsy the body was that of an emaciated elderly white female appearing to be about 80 years of age There were no unusual features except those associated with her advanced age When the pleural cavities were opened about 3 000 ml of straw colored fluid was removed from the left pleural cavity The entire pleural surface of the left side was studded with myriads of small firm gray nodules measuring up to 4 mm in diameter Similar but fewer nodules were present on the pleura of the right side Within the pericardium there was about 200 ml of straw colored fluid and the entire left side of the pericardial sac was thickened fibrotic and firmly adherent to the visceral pleura of the left lung

The left lower lobe of the lung was greatly retracted and shrunken. It was a firm, gray, consolidated mass, irregularly streaked with darker gray and red. The left upper lobe was also shrunken but it contained many small gray nodules measuring from 1 to 2 mm in diameter up to 1 cm in diameter. The entire right lung showed similar, small gray nodules scattered over the pleura and throughout the parenchyma. The trachea and both main stem bronchi were filled with thick, yellow exudate. The hilar lymph nodes were small and anfractuous. As we shall see later, when the slides are shown, this was a bronchiolar carcinoma probably primary in the left lower lobe with metastases to the other lobes, pleura, and hilar nodes.

Figure 1 (A) Section of bronchiolar carcinoma from primary site in left lower lobe of the lung ( $\times 100$ ) (B) Higher magnification of tumor cells from same area ( $\times 430$ )

The other pathologic features were those associated with the woman's advanced age. These consisted of severe calcific atherosclerosis in the thoracic and abdominal aorta, atrophy of the genitalia, multiple polyps in the cecum and sigmoid colon, sigmoid diverticuli, and giant

rugular folds in the stomach. The mass palpated in the right flank was actually a pyramidal shaped right lobe of the liver which extended down to the brim of the pelvis. The liver was only 1 110 grams in weight and was not unusual. A soft red polypoid elevation in the stomach 1 cm in diameter was present.

We will show some representative slides of the tumor and its metastases. The first section (fig 1A) is from the left lower lobe where we believe the primary was. As you can see the tumor takes glandular structures of varying sizes and shapes. The tumor epithelium is rather neat and resembles bronchial epithelium remarkably (fig 1B). In areas where the tumor has apparently been present a long time the tumor cells are in small clumps and are generally large pleomorphic and anaplastic (fig 2). In these areas there is a generous fibrous re-

Figure 2. Clump of anaplastic pleomorphic tumor cells in left lower lobe of the lung (X 430)

sponse. In all of the sections of the right lung and left upper lobe the tumor radiated out from around blood vessels and bronchi, indicating that it probably arrived there via perivascular and peribronchial lymphatics.

Verastases were present in the pleura, hilar lymph nodes, pericardium, aorta, and diaphragm. In addition, the patient had acute tracheitis and bronchopneumonia. Other significant findings were chronic hypertrophic gastritis and adenomatous polyps of the stomach. Multiple adenomatous polyps were present in the colon, and there were multiple dermoid cysts adjacent to both fallopian tubes. The pituitary showed eosinophilia and a remnant of Rathke's pouch.

This is a rather typical case of bronchiolar or alveolar cell carcinoma of the lung. This tumor is said to constitute between three and four per cent of malignant tumors of the lung.<sup>1</sup> Dyspnea is usually the first symptom, and death is more often produced by local effect on the lung tissue than by metastases. The peripheral location, and usual failure to metastasize widely, despite massive involvement of both lungs distinguish this tumor from the bronchogenic carcinomas.

#### Pathologic diagnoses

- 1 Bronchiolar (alveolar cell) carcinoma of the left lower lobe
- 2 Metastases to both lungs, pleura, diaphragm, pericardium, hilar nodes, and aorta

## SERVICE ARTICLES

# AN EFFECTIVE MOTOR VEHICLE ACCIDENT PREVENTION PROGRAM

GEORGE B RIBBLE *Captain MC USN*

THE average driver rolling down the highway in his car seems unaware of the mortal danger that may lie just ahead of him. While death rates per 100,000 miles have decreased since 1935, the magnitude of the slaughter keeps mounting because of the increased number of cars and the increased number of people exposed to potential accidents. The seriousness of the problem is shown by the fact that more lives have been lost through vehicular accidents than in all the wars the United States has fought since the Revolution—over one and one half million. Nor is the loss of life confined to adults who usually share some of the responsibility for their fate. In 1954 the automobile was responsible for about 2750 of the 6000 deaths caused by accidents among children from 5 to 14 years of age. In spite of the large number of lives lost from this cause, the public exhibits a strange apathy as compared with its concern over the common childhood diseases, which are less important as causes of death and disability.

Recently, general interest in the problem of automobile accident reduction has really increased, particularly in the medical and related professional groups. For example, in 1954 Chapman<sup>1</sup> emphasized the epidemiologic approach to traffic safety and Blasdell<sup>2</sup> called for a reappraisal of the problem in terms of human capacity with adoption of rigid driver training programs and more stringent highway regulations. Holland and Long reported that traffic accidents are the principal peacetime cause of death in the Army. In 1954 they accounted for 691 deaths, or nearly one third of the 2346 total for that year.

Sheloen<sup>3</sup> cited prevention as the only cure for head injuries from automobile accidents and pointed out that there were more deaths in 1953 from auto crashes than from all forms of poliomyelitis and tuberculosis combined. In emphasizing the responsibility of the medical profession he stated that if this Nation were confronted with an epidemic that took the lives of 38000 persons in one year and the medical profession did not recom-

trend steps to control the situation, there would be a congressional investigation

Dietrich<sup>4</sup> emphasized the necessity of early childhood training to develop an attitude of safety consciousness. He also recommended the teaching of accident prevention in medical schools, to instill in members of the profession a proper awareness of the threat to health presented by accidents. McInrland<sup>5</sup> stressed the human element in automobile accidents, calling attention to the interrelationship of the driver, his vehicle, and the environment. He recommended carefully controlled experimental studies, epidemiologic surveys, and statistical analysis, with dynamic and continuous safety programs producing positive results from such studies.

McGuire<sup>6</sup> contributed outstandingly to our knowledge of human factors in traffic accidents. He found that a disproportionate number of accidents involving Marine Corps personnel at Camp Lejeune, N. C., occurred in the lower ranks, which are usually made up of young men. He confirmed the suspicion that accidents frequently are precipitated by physical fatigue and abuse of alcohol, and usually are associated with traffic violations. He also indicated that drivers who do not have accidents comprise a special group who have respect for law and who come from a harmonious family environment. They are, in general, friendly and co-operative persons with temperate and socially acceptable attitudes. He advocated careful psychology examination of drivers to eliminate the unfit, and suggested that training programs be instituted to improve borderline individuals.

Interest in traffic safety has increased in the military services. In May 1954 the Commandant of the Marine Corps issued a directive<sup>7</sup> outlining a program for auto accident prevention at all Marine Corps activities. It calls for the organization of Safe Driving Councils at local commands to advise on the implementation of educational, enforcement, traffic engineering, and administrative control measures. Four hours of basic instruction under the supervision of local "Unit Vehicle Accident Prevention Officers" is required annually for Marine Corps personnel in the lower ranks. Operators of civilian as well as of military vehicles are included. The program is specifically directed to the prevention of accidents among military personnel, irrespective of their duty status.

In January 1956 the Bureau of Naval Personnel issued a similar instruction,<sup>8</sup> which applies to all naval activities. Thus, both branches of the naval service have extended the responsibility of local commanding officers to include the prevention of injuries and deaths from traffic accidents.

In a previous article,<sup>12</sup> I reported the value of a safe driving program at the Naval Air Station Memphis, Tenn., during the period 1951 to 1954. This station included several military activities with a total of about 10 000 personnel. A large proportion were young men who had left home only recently and were not fully accustomed to the lack of parental restraint. Most of these youngsters did not hesitate to gamble in traffic for a week end at home or a "liberty" in the Memphis vicinity. During my first year or board about 300 persons received major and minor injuries, and 15 were killed. As Medical Officer of the Station Dispensary I realized that my greatest challenge was to reduce the large toll of casualties from automobile accidents. The organization of a Safe Driving Council and the success obtained in reducing the annual toll has been described previously.<sup>12</sup>

When I arrived at this air station in May 1954, much interest in the traffic safety program was evident. Talks were being given and films on safe driving were being shown to small groups of men as part of the required four hours' annual basic instruction. A sound enforcement program was in effect and good general publicity and educational information were being disseminated via a local radio station and through the station newspaper, the *hindsuck*. An auto accident score board also was employed in attempting to reduce accidents among personnel.

A suggestion that a device be set up for the broadcasting of admonitions on safe driving to men leaving the base for leave or liberty was quickly accepted. This had proved to be of value at the Naval Air Station Memphis, Tenn. Its use on Fridays and the long holiday week ends has been continued as a regular part of the safe driving program. Display of an ambulance and a wrecked vehicle combined with verbal admonition, makes a dramatic and effective appeal to a man at the key moment of departure from the station.

Throughout the year 1955 every effort was made to implement General Order No 152.<sup>13</sup> Officers in charge of instruction were provided with a complete outline of education literature, such as speech kits, booklets, films, charts, and many other items used in carrying out the local program.

To efficiently implement the order and to immediately influence as many men as possible a general rally of about 4 000 low rated younger men was held in the station theater in March 1955. The attendees were told of the traffic danger on and off the station and were asked to co-operate by driving safely. This proved to be a simple and practical way to influence a large number of the most susceptible group. In September 1955 the policy was established of having a rally before each national

holiday or long week end During the national holiday periods of the year 1955, the auto accident toll of the station was at its lowest Figure 1 summarizes the record of the station for the major holiday leave periods

Figure 1 Low automobile accident toll during major holiday leave periods in 1955

Throughout 1955, pamphlets obtained from various automobile manufacturers and life insurance and casualty companies were distributed to the crew. In addition, a striking pictorial pamphlet with photographs of accident victims was prepared by local safety agencies. This was financed by the advertising of local merchants, and over 5,000 copies were distributed. Educational literature of this type was used to supplement weekly articles in the *Windsock*. Posters and other written material designed to bring about an improved attitude of driver safety consciousness helped to reinforce local command programs.

#### ACCIDENT FACTS

A pin map (fig. 2), showing where accidents had occurred during 1955, helped us to realize our problem. This map was posted in the Commanding General's weekly conference room. An analysis of the 1955 casualties (table 1) shows that the greatest number of accidents occurred in local area, but that distance driving resulted in more fatalities per accident. Analyses of injury and death rates for the various subcommands of the station

## ROLE OF THE MEDICAL OFFICER

In considering the role of the Medical Officer in motor vehicular accidents, prevention is the most important role. Figure 4 lists specific areas in which the Medical Officer can be used to aid various branches of the Safe Driving Council and adviser to the Commanding General on medical aspects of traffic accidents. The Medical Officer's knowledge of the problem gained through personal experience and statistical analysis is of great value in bringing attention to the importance of causative factors and to instill optimism and confidence.

### The Medical Officer—MEMBER SAFE DRIVING COUNCIL

Applies PRINCIPLES OF EPIDEMIOLOGICAL APPROACH TO PROBLEM OF AUTOMOBILE ACCIDENTS

Assembles STATISTICS ON INJURIES AND DEATHS

Studies CONTRIBUTING FACTORS SUCH AS ALCOHOL AND FATIGUE AND MAKES RECOMMENDATIONS

Helps ELIMINATE DRIVING WHILE DRINKING BY EXPEDITING MEDICAL EXAMINATION

Effects LIAISON WITH CIVILIAN RESEARCH PROGRAMS TAKES PART IN LOCAL COMMUNITY PROGRAMS

Assumes ROLE OF LEADERSHIP IN STIMULATING INTEREST AND ACTION ON CONTROL MEASURES

The Medical Officer in prevention of motor vehicle accidents brings into the participants in a program Conviction at the highest level defined as "command interest," has been found to be absolutely essential. It overcomes the inertia usually prevalent at lower levels of command from too long familiarity with and forced acceptance of the situation. As a member of the Safe Driving Council the Medical Officer's recommendation to the Commanding General possesses the benefit of the collective opinion of other council members and are more likely to withstand critical examination.

Experience at many military installations and at city, state, and national level has proved the beneficial effect of safety programs based on intensive efforts through the "three E's."

Education, Enforcement, and Traffic Engineering At military activities, we have another avenue, "Administration," which implies the power of military command to exercise certain control measures that are not practicable in a civilian community. Such programs, as outlined by the National Safety Council or by high military command, can usually be implemented in large portion by using personnel and facilities already present at the local activity. Thus, at minimum expense, savings of incalculable value may be obtained through intensive local programs. It is only necessary to convince responsible local authorities of the wisdom and promise of this course of action to ensure beneficial results. Injury from automobile accidents is a life and death matter, lying squarely in the province of the physician.

### SUMMARY

Injuries and deaths caused by motor vehicle accidents constitute a serious national and military problem that to date has not received its proportionate share of attention.

At a military base, an accident prevention program such as described herein can reduce injuries and deaths from motor vehicles at minimum cost, using facilities and personnel for the most part already available.

*The military medical officer has an important key to a successful reduction in casualties in his influence with the top echelon of command, whose support in implementation of a control program is an absolute essential.*

# VITAMINS IN INFECTIONS

The influence of vitamin nutrition on resistance to specific infections in the human subject remains largely unknown. There is considerable evidence that infections and other stress situations influence the requirement or utilization of certain vitamins but there are few if any data regarding exact requirements in specific pathologic states. The therapeutic value of administration of large doses of vitamins in infections has not been appraised critically.

# RIFLE-SLING PALSY IN MARINE CORPS RECRUITS

ERWIN L BURKE *Lieutenant MC USN*  
CLARENCE G GLENN *Lieutenant Commander MC USNR*  
JAMES F WALES *Lieutenant MC USNR*

THE condition of rifle sling palsy was brought to our attention by the simultaneous presence on the Neurology Ward at this hospital of five Marine Corps recruits with severe disability of the left hand and arm following use of the rifle sling in training. Ten additional recruits with this condition were treated at this activity in the past three years. As shown in table 1, the length of hospitalization is often prolonged.

Figure 1 Rifle sling palsy is caused by the loop sling which is placed tightly about the left arm in the manner and position shown. The greatest pressure is exerted posteriorly and the least pressure is applied anteriorly by reason of traction upon the sling. This explains the involvement of the radial, ulnar, median, and musculocutaneous nerves in that order of frequency.

From U S Naval Hospital, San Diego, Calif. and Weapons Training Battalion, Marine Corps Recruit Depot, San Diego, Calif.

TABLE 1 Analysis of 15 cases of rifle shrapnel palsy admitted to this hospital in the past three years

Patient	Nerves involved	Hospital days	Duration of symptoms in days prior to hospitalization	Remarks

*Figure 2 The loop type sling is not used in the standing position. We believe that the "ready sling" shown is harmless. The rifleman pictured has the typical slender habitus most commonly seen in patients with this disorder.*

*Figure 3 This man had radial, ulnar, and median nerve palsy necessitating prolonged hospitalization. Note the wrist drop found in radial nerve palsy and the "lateral drift" of the little finger seen in ulnar nerve palsy.*

Figure 4. The presence of median nerve palsy can be demonstrated by the inability of the patient to adduct the involved thumb to form a bridge in the manner shown.

Figure 5. Areas of sensory loss seen in a case of radial and ulnar nerve palsy.

The above findings are contrasted with those of Muntz, Conrad, and Murchison,<sup>1</sup> who reported 18 cases of rifle sling palsy occurring in soldiers and found that the time for full recovery varied from 1 to 21 days, with a mean of 5.4 days. In our series, there was a mean of 96 days before full recovery or separation from service.

In order to obtain a reliable estimate of the frequency of occurrence of this condition a study of Marine Corps recruits finishing the prescribed course of rifle training exercises was carried out. The power of dorsiflexion of the wrist was used as a screening test, and where significant weakness was found a test of ulnar and median nerve function was also carried out.<sup>2</sup> Of 1,213 men who were screened, 97 (7.9 per cent) were found to have some nerve deficit. Seventy-nine had radial nerve involvement only, 17 had combined radial and ulnar nerve involvement, and 1 had radial, ulnar, and median nerve involvement. Eight of the 97 had sufficient disability to interfere with the performance of their duty. Two of these 8 had marked weakness of radial nerve function. At follow-up examination three weeks later the last two men were the only ones with significant remaining disability.

The difficulty of screening a large number of men in the manner described is that it is time consuming and admittedly subject to various errors. A more objective and practical approach could be utilized by having the drill instructors test the ability of groups of men finishing firing exercises to support the rifle by the sling with the wrist extended 180°, palm down. The average man can carry out this maneuver with ease. All subjects unable to do so could then be referred to the dispensary for examination by the medical officer.

We also believe that the drill instructors could profitably be made aware of this condition and could take steps to assure loosening of the sling after rifle firing exercises.

#### SUMMARY

In a study of 15 Marine Corps recruits hospitalized with severe rifle sling palsy, the duration of disability was found to be prolonged.

The screening of 1,213 men for rifle sling palsy following the prescribed course of rifle training exercises revealed some nerve deficit in 97 (7.9 per cent). There was sufficient disability to interfere with performance of duty in 8 (0.7 per cent), however all but two recovered within three weeks.

In the light of this and other studies we suggest that the "tourniquet" type rifle sling bears re-evaluation and should be used with at least the same precautions as a tourniquet.

Figure 4. The presence of median nerve palsy can be demonstrated by the inability of the patient to abduct the involved thumb to form a bridge in the manner shown.

Figure 5. Areas of sensory loss seen in a case of radial and ulnar nerve palsy.

The above findings are contrasted with those of Muntz, Conrad, and Murchison,<sup>1</sup> who reported 18 cases of rifle sling palsy occurring in soldiers and found that the time for full recovery varied from 1 to 21 days, with a mean of 5.4 days. In our series, there was a mean of 96 days before full recovery or separation from service.

In order to obtain a reliable estimate of the frequency of occurrence of this condition a study of Marine Corps recruits finishing the prescribed course of rifle training exercises was carried out. The power of dorsiflexion of the wrist was used as a screening test, and where significant weakness was found a test of ulnar and median nerve function was also carried out.<sup>2</sup> Of 1,213 men who were screened, 97 (7.9 per cent) were found to have some nerve deficit. Seventy-nine had radial nerve involvement only, 17 had combined radial and ulnar nerve involvement, and 1 had radial, ulnar, and median nerve involvement. Eight of the 97 had sufficient disability to interfere with the performance of their duty. Two of these 8 had marked weakness of radial nerve function. At follow up examination three weeks later the last two men were the only ones with significant remaining disability.

The difficulty of screening a large number of men in the manner described is that it is time consuming and admittedly subject to various errors. The average man can carry out this maneuver with ease. All subjects unable to do so could then be referred to the dispensary for examination by the medical officer.

We also believe that the drill instructors could profitably be made aware of this condition and could take steps to assure loosening of the sling after rifle firing exercises.

#### SUMMARY

In a study of 15 Marine Corps recruits hospitalized with severe rifle sling palsy, the duration of disability was found to be prolonged.

The screening of 1,213 men for rifle sling palsy following the prescribed course of rifle training exercises revealed some nerve deficit in 97 (7.9 per cent). There was sufficient disability to interfere with performance of duty in 8 (0.7 per cent), however all but two recovered within three weeks.

In the light of this and other studies we suggest that the "tourniquet" type rifle sling bears reevaluation and should be used with at least the same precautions as a tourniquet.

The population of the United States has been increasing steadily and is expected to continue its vigorous growth in the next two decades. Since the last census was taken five years ago our population including the Armed Forces overseas has increased by approximately 13<sup>1</sup>/<sub>2</sub> million and now totals more than 164<sup>1</sup>/<sub>2</sub> million. If the birth rate continues at its present high level the population of our country will pass the 200 million mark before 1970 and will exceed 220 million by 1975. Such increase in the next 20 years would be equal to the gain in the preceding third of a century.

# ARMY AEROMEDICAL EVACUATION

THOMAS N PAGE, *Colonel MC USA*

SPURGEON H NEFL *Lieutenant Colonel MC USA*

**T**ODAY, the United States Army is in a state of revolutionary change. With the advent of new weapons systems, including delivery of nuclear weapons in both the kiloton and megaton range by a variety of means, it is apparent that the Army of the future, if it is to survive (much less accomplish its mission) on the battlefield of the future, must undergo radical changes in organization, dispositions, and employment. New concepts are based essentially on two inescapable facts. Enemy capabilities for the employment of mass destruction weapons dictate that the Army of the future must be capable of increased dispersion and possess the organic mobility to mass for attack at points of decision and then disperse again to avoid annihilation. This situation establishes a requirement for increased use of organic Army aviation, not only to facilitate tactical mobility, but also to increase the capability, efficiency, and responsiveness of logistic support, including medical evacuation. The following represents the considered opinion of the Surgeon General of the Army with respect to the subject of Army aeromedical evacuation.

## ARMY AEROMEDICAL EVACUATION

A brief review of the historical development of Army aeromedical evacuation will assist in the understanding of the current concept. The Army has long recognized the advantages of aeromedical evacuation, but until recently has not had available aircraft in sufficient numbers for its exploitation in the forward combat area. The feasibility and full advantages of aeromedical evacuation by high performance, fixed wing aircraft became apparent early in World War II. Immediately after that conflict, aerial evacuation was designated as the primary means for moving patients to the rear of the combat zone. This mission has been most effectively accomplished by U S Air Force troop carrier elements within overseas theaters, and by the Military Air Transport Service between theaters and within the continental United States. Pending development of the helicopter and the assault type aircraft there remained,

---

From the Office of the Surgeon General Department of the Army Washington O C

however, little capability for the forward aeromedical evacuation function.

In Korea circumstances demanded that the advantages of aerial evacuation be extended into the most forward combat area. The paucity and disposition of Army treatment facilities, the nature of the terrain, the type of combat, and the extremely limited surface communications net all combined to establish an urgent requirement for a rapid, atraumatic, dependable means for moving casualties from forward medical facilities to Army hospitals capable of providing definitive lifesaving surgery. These considerations, plus the acceptance of the helicopter as an organic vehicle of the Army, permitted the fulfillment of an old concept of the Army Medical Service.<sup>1</sup>

Shortly after the outbreak of hostilities in Korea, a helicopter detachment of the Third Air Rescue Squadron began to receive requests from ground elements for the evacuation of casualties from difficult terrain. Inasmuch as this detachment was not fully occupied with its primary mission, it responded to these calls. By August 1950 this U. S. Air Force unit was answering so many calls that it found itself in the medical evacuation business.

Quick to note the advantages of helicopter evacuation in terrain such as Korea, the Eighth Army developed an increased interest in the program. After a significant test conducted by Army and Air Force representatives on 3 August 1950 in the school yard of the Taeju Teachers College, Army helicopters were adopted for the evacuation of casualties and the first procedures were established. In January 1951 the first Army helicopter detachment with a primary mission of medical evacuation became operational, followed in rapid succession by two others.

These nonmedical units were assigned to the Eighth Army Flight Detachment, were attached to forward surgical hospitals, and were under the dispatch/operational control of corps surgeons. In August 1952 the Department of the Army authorized the "helicopter ambulance unit," a T O & E (Tables of Organization and Equipment) organization derived from the Korean experience. In December 1952 the operating helicopter evacuation detachments in Korea were redesignated as "medical detachments helicopter ambulance" and became medical units for the first time.<sup>2</sup> During this period similar detachments were activated within the continental United States and some dispatched to the Seventh Army in Europe.

With only minor changes, the medical helicopter ambulance detachment of today (of which there are 11) is almost identical with that authorized in 1952. In the near future it is expected that a "Medical Aerial Ambulance Company" will be authorized.

for the forward aeromedical evacuation mission. This unit, equipped with utility helicopters, will be allocated to the field army to supplement current helicopter ambulance detachments. It is believed that considerable operational, administrative and logistic advantages will accrue from the company type organization.

This rather brief historical account brings us to current Army Medical Service doctrine pertaining to forward aeromedical evacuation. These doctrinal statements have been developed after thorough evaluation of experience data, current doctrine and procedures in the light of what is known of warfare of the future.

*Aeromedical evacuation within the combat zone is an accepted mission and capability of organic Army aviation.* The "Memorandum of Understanding relating to Army Organic Aviation" between the Secretaries of the Army and the Air Force, dated 4 November 1952, states that the Army will provide "aeromedical evacuation within the combat zone, to include battlefield pickup of casualties, their air transport to initial points of treatment and any subsequent move to hospital facilities within the combat zone." The medical evacuation mission of Army aviation was recently affirmed by the Secretary of Defense.

*Warfare of the future will be characterized by an increased use of organic Army aviation for both emergency and routine aeromedical evacuation within the combat zone.* This is in consonance with the increased dispersion of tactical and logistic support units and the increased dependence upon aerial lines of communications.

*Within the Army, the Army Medical Service has the basic technical responsibility for all medical evacuation, whether by surface or aerial means.* In order to ensure selectivity of evacuation and timeliness of treatment, the medical service must retain control over all evacuation, to include as a minimum the designation of patients to be moved, forward pickup sites, destination hospitals, and the provision of medical attendants and equipment.

*The current concept for accomplishing the Army aeromedical evacuation mission (i.e., emergency evacuation of seriously wounded by organic medical aircraft, and support by nonmedical aviation elements upon the request and under the jurisdiction of the medical service) is more desirable than certain previously proposed concepts of elimination of organic medical aviation, making all aeromedical evacuation the exclusive mission of nonmedical Army aviation units.* Specifically, the proposed concepts (1) place the welfare of patients secondary to other logistic considerations and missions, which is contrary to the national philosophy and detrimental to individual and unit morale, (2) lack responsiveness to emergency evacuation requirements,

(3) reduce medical control over the movement of patients, which reduces selectivity in evacuation, delays ultimate treatment and leads to overevacuation, depleting combat strength, (4) preclude most effective utilization of critical medical means including professional specialists and available hospital support, (5) fail to provide adequate property exchange concurrent with evacuation, reducing the continued capability of forward mobile medical treatment facilities, and (6) require diversion of logistic and tactical aircraft to missions for which they may not be designed or configured reducing the effectiveness of over all Army aviation support.

*The Army Medical Service requires sufficient organic aviation of the proper type to enable it to accomplish its continuing mission of rapid evacuation of the severely wounded directly to appropriate medical treatment facilities.* Ambulance aircraft should not be special purpose from the design or procurement standpoint but should be single purpose in the operational sense that they will not be used for any but medical missions. Ambulance aircraft should be marked with Geneva Red Crosses and should be manned with medical crews, including pilots, to afford additional protection to patients and to medical facilities where they may land. This provision of single purpose ambulance aircraft is considered no more uneconomical than the provision of fire fighting trucks and field ambulances, by the Army, or air and sea rescue aircraft by the Air Force and Navy.

*In the future both fixed and rotary wing ambulance aircraft will be required for the combat zone aeromedical evacuation mission due to the increased dispersion of tactical formations and supporting medical treatment facilities and the need for maximum flexibility, reliability and selectivity in medical evacuation.*

*Ambulance helicopters are required for the forward pickup of casualties and their transportation to initial points of treatment and to hospitals capable of resuscitative surgery.* Such helicopters should possess a small silhouette be capable of transporting two litter patients and one medical attendant internally and capable of flight under marginal weather conditions. The Bell AH 40 helicopter which should be available soon is well suited for this mission. Pending the availability of an adequate utility helicopter it is believed that a combination of the capabilities of current reconnaissance and utility helicopters will minimize the limitations of each type aircraft.

*Ambulance airplanes are required primarily for the longer lateral and rearward movement of patients needing special surgical treatment that may not be available in every forward hospital or to bypass intermediate hospitals with long surgical lags.* In addition they improve the flexibility and selectivity as well as the economy

and reliability of all forward aeromedical evacuation. The increased speed, range, and stability of fixed wing aircraft, their reduced initial and maintenance cost, and reduced sensitivity to wind velocity and differential more than compensate for their increased landing site requirements and their relative sensitivity to ceiling and visibility minimums. Such utility aircraft would operate from landing strips already prepared for other tactical and logistic purposes.

*The company type organization for the aeromedical evacuation function is superior to the current cellular detachment concept. Characteristics inherent to Army aircraft permit centralized command control, and considerable administrative, logistic and operational advantages may be achieved.*

*Medical air evacuation units, either fixed or rotary wing, should be assigned to the field army, to permit full exploitation of their capabilities and to facilitate shifting of evacuation support to meet actual requirements. Attachment to major subordinate commands should be limited to isolated or independent operations when centralized control of evacuation is infeasible.*

*The current procedure for requesting emergency aeromedical evacuation missions is adequate, but electronic means need considerable improvement to increase their reliability. The consensus is that there is no real requirement for a separate communications net for the control of aeromedical evacuation. The use of common electronic means is more economical, and other than medical agencies are involved in and should know about medical evacuation missions.*

*The Army Medical Service does not require sufficient organic aviation for the entire Army aeromedical evacuation mission. The movement of nonemergency patients by air can be accomplished economically by making use of utility and cargo aircraft in conjunction with normal logistic missions, provided there is adequate medical control over the movement of patients. To the extent feasible, all Army aircraft should be designed so as to be capable of transporting patients when required and upon the request of the medical service. Aeromedical evacuation should be retained as a secondary capability and mission of appropriate Army aviation units, to provide economical aerial movement of non-emergency patients when surface evacuation means are nonexistent or inadequate.*

*The Army Medical Service must maintain jurisdiction over all Army aeromedical evacuation, regardless of the category of the patient or the source of the aircraft. This does not imply actual medical control of nonmedical aircraft, but does include such matters as the designation of forward pickup sites and rearward destinations, provision of necessary medical personnel and equipment, and surveillance of casualties in flight. All movement of*

patients must be planned, programmed and controlled. Beebe and DeBakey stated "Nonselective evacuation of battle casualties undertaken for bed clearance measured by transport capacity, timed by transport availability and followed by distribution to hospitals based on bed credits, invites wound complications, retards recovery, and prevents return to duty."<sup>1</sup>

The selectivity which is inherent to Army aeromedical evacuation must be emphasized. This characteristic is less appreciated than the more obvious advantages of speed, range, and flexibility. Actually it is a function of these three factors. With adequate medical control of forward aeromedical evacuation the individual casualty is no longer "doomed" to evacuation to that particular hospital which happens to be in support of his unit. He may now be moved rapidly and safely to that hospital facility best staffed, equipped and situated for the care of his particular type of wound. This in effect places specialized surgical treatment in direct support of every forward surgeon.

This selectivity further promotes the effectiveness and economy of forward medical service. Specialist personnel may now be concentrated in designated facilities, and there is no requirement for staffing each hospital for the care of every type of patient. Surgical lags may be minimized and the patient loads equalized among available hospitals. The capabilities of forward treatment facilities are preserved by effective property exchange. The mobility of forward medical facilities is improved by the existence of a means for rapid atraumatic evacuation of large numbers of patients, permitting such units to displace without leaving large holding detachments.

# AUTHORITARIAN ATTITUDES AND ADJUSTMENT IN A MILITARY SITUATION

FRANCIS M. CANTLER *Captain USC USA*  
ANNE N. CANTLER *B. A.*

IT IS AN operating assumption that certain general attitudinal dispositions contribute to the effectiveness of individual adjustment to various life situations. One situation of particular interest, if only because nearly everyone at one time or another must make an adjustment to it, is the military situation. Although the military situation encompasses a wide range of specific "environments," one prevailing characteristic is its definite and rigid structuring, clear and known level and degrees of authority, and a body of rules and regulations governing nearly every aspect of living, with its demands on the individual clearly set forth.

One particular attitudinal disposition which might be related to the effectiveness of adjustment to this structured military situation is the so-called "authoritarian" attitude. The "authoritarian" individual has been described as one who is most comfortable in closely structured situations with strong central authority figures, continual ordering of all aspects of life, et cetera. In addition, there have been a number of other, more or less uncomplimentary, characteristics attributed to these individuals, e.g., Frenkel-Brunswik's<sup>1</sup> conclusion that authoritarians are inflexible, repressing, insecure, essentially anxious and possess other tendencies suggesting emotional instability if not outright neurosis. Much previous research in this area is conflicting with respect to the relationship between authoritarian attitudes and adjustment. Minsling<sup>2</sup> concluded that there is no direct relationship between authoritarianism and mental health. Siegel<sup>3</sup> found a positive relationship between authoritarianism and a measure of anxiety, while Stotsky,<sup>4</sup> using the same instruments, found a negative relationship.

While authoritarianism in the sense described above is not merely the same thing as "attitude toward authority," many of the same attitudinal dispositions are probably involved. The question arose as to what, if any, relationship authoritarian attitudes might bear to actual adjustment to such an "authority" situation as the military one.

### Adjusted Group

*Normal group (A)* This group was composed of 271 enlisted soldiers who were operating personnel of a large Army general hospital. It was an unselected group in the sense that it represented all of the available personnel of the hospital who could be obtained for the study, and they were not volunteers in any sense other than in agreeing to cooperate in the completion of the questionnaire instrument.

The delinquent group and the normal group were drawn from the same parent population, i. e., personnel of a large, medical post "Service" troops (i. e., Medical, Signal, Transportation, Quartermaster, et cetera) composed 76 per cent of the psychiatric patient group and "line" troops (Infantry, Artillery, et cetera), 24 per cent. Among the service troops in this patient group, six were Air Force personnel, there were no Air Force personnel in the other groups. The proportions of U. S. (Selective Service) versus R. A. (Regular Army) are approximately the same in each group (10 per cent of the delinquent group, 38 per cent of the patient group, and 15 per cent of the normal group, were "U. S." personnel).

The test used in the study was the California F Scale, developed and described by Adorno and associates and is composed of the 29 items presented as Forms 45 and 10 in "The Authoritarian Personality."

The subjects in group N completed the scale in group sessions. They were asked to cooperate in a research study, and were assured of anonymity, but were requested to state age, years of education, length of service, military rank, and whether they were U. S. or R. A.

The subjects in group D completed the scale in individual sessions. They were asked to assist in gathering information on items of general interest and were assured that the results would have no bearing on their trial, nor could the results be introduced as evidence in any way.

The subjects in group P completed the scale in individual sessions as part of a psychological testing procedure. Assurance as to anonymity was not given in the same way as to the other two groups because of the special conditions of psychiatric evaluation, but subjects were assured that the results of the study would be medically confidential.

The composition of the three groups with regard to age, education, length of service and military rank is presented in table 1. There is no statistically significant difference between means on any of the variables, and the groups are therefore comparable in these respects.

This article is a report of an investigation of authoritarian attitudes in certain military groups with differing types of adjustment to the military situation. Assuming that authoritarianism represents a fairly basic attitudinal disposition, the finding of a relationship between this attitude and military adjustment could point the way toward further investigation with the eventual hope of identifying specific predictive factors.

### MATERIAL AND METHOD

Two general types of "maladjustment" were selected for study. One group represented maladjustment in the sense of overt rebellion or disregard of the military rules *i e* individuals in disciplinary difficulties. Another group represented maladjustment in the sense of disturbed inner adjustment not manifested by overt rebellion *i e*, individuals with certain psychiatric disorders. A third, normative group represented individuals who were functioning adequately and with no known maladjustment.

#### Maladjusted Groups

*Delinquent group (D)* This group was composed of 50 enlisted soldiers who were convicted by special court martial proceedings of a variety of offenses ranging from AWOL to aggravated assault with many instances of insubordination, disregard of orders *et cetera*. Most of these soldiers were second and third time offenders. There were no instances of very serious offenses such as burglary, homicide, *et cetera*. Many of the offenses were of a strictly military nature. This delinquent group is probably not comparable to a civilian "criminal" group or even to civilian delinquent groups except for certain cases. Many of the offenses in this group would not be legal offenses in a civilian setting *e g* absent without leave, insubordination to an authority figure, disregard of orders *et cetera* though the individuals would probably be equally maladjusted.

*Psychiatric patient group (P)* This group consisted of 100 enlisted soldiers who were seen in psychiatric consultation. These patients were characterized by a variety of diagnoses in the general categories of psychoneurosis or character disorder. All patients diagnosed as psychotic, all those in whom there was a question of neurological involvement, and all who were being evaluated pending court martial or other disciplinary action were omitted. The great majority of the patients had never had disciplinary action of any sort and most important, in no case was the psychiatric evaluation requested because of or related to delinquent behavior. In each of the 100 patients, anxiety was mentioned as one of the most prominent features. In most instances, special difficulties in adjusting to one aspect or another of military life were also mentioned *e g* difficulty in accepting discipline, forced separation from family, dislike of military assignment, *et cetera*.

F Scale score. In none of the groups is there a statistically significant difference between Selective Service and Regular Army troops in total F Scale score.

The distribution of the normal group was relatively symmetrical and somewhat platykurtic. The distribution of the patient scores was markedly skewed, with the low score end of the distribution missing. Distribution of delinquent scores was symmetrical but very platykurtic.

Product moment correlations between total F scale scores and educational level are, for the normal group, 0.11, for the delinquent group, 0.03, and for the patient group, 0.12. These correlations are statistically significant in the case of both patient groups. In the normal group, correlation with age is 0.11, with length of service, 0.15, and with rank, 0.07. The correlation with length of service is significant at 0.01 level of significance. Perhaps the most interesting feature of these correlations is not that there are some statistically significant ones, but that the relationships are so very small, in view of what has been written about the relationship of F Scale responses to intelligence, education, status, environmental influence, et cetera.

In general, there is evidence of a definite relationship between authoritarianism as reflected in F Scale responses, and the type of adjustment manifested by the groups studied, with the greatest difference found between the delinquent and the neurotic types of maladjustment.

The finding of high authoritarian attitudes in the patient group is not an unexpected finding in view of past descriptions of the authoritarian individual as an essentially neurotic person. However, the delinquent group is an equally neurotic group in terms of their inadequate adjustment to the realistic life situation in which they find themselves. Hence there seems to be an attitudinal parallel to the real difference between expressions of tensions in overt antiauthority actions and developing anxiety or psychosomatic symptoms.

One possible clue to this difference is a recent study by Bass,<sup>6</sup> who concluded that acquiescence or compliance accounts in large part for the direction and degree of F Scale responses. If it is true that the F Scale measures compliance rather than authoritarianism, the results obtained in the present study indicate that the normal group is a moderately compliant group, the patient group extremely compliant, and the delinquent group a rather uncompliant one, results which certainly reflect the adjustment situation. An authoritarian attitude (or even a lack of moderate degree) could mean ability to be dominated rather than be broken by it, regarded as neurotic, except where it is

TABLE 1 Age education length of military service and rank of subjects in the delinquent psychiatric patient and normal groups

	Group		
	Normal	Patient	Delinquent
Number of subjects	274	100	50
Age (years)			
Mean	26.86	25.38	23.96
Standard deviation	7.36	6.56	5.16
Education (years)			
Mean	11.91	11.64	11.36
Standard deviation	4.50	1.92	1.29
Service (months)			
Mean	65.00	44.58	31.54
Standard deviation	59.98	41.97	23.66
Rank			
Mean	2.83	2.52	1.92
Standard deviation	1.50	1.37	1.06

Lowest enlisted grade (Private) 1 and highest enlisted grade (Master Sergeant) 6

## RESULTS AND DISCUSSION

In table 2 are presented the mean scores of each group with the standard deviation and range of scores obtained. These data were subjected to a simple two part analysis of variance which yielded an F ratio of 19.168. This ratio is significant beyond the 0.01 level of confidence.

TABLE 2 Total item scores attained on California F Scale by normal psychiatric patient and delinquent group

Group	Number of subjects	Range	Mean	Standard deviation
Normal	274	39-194	128.58	31.34
Patient	100	96-184	140.62	18.44
Delinquent	50	62-161	111.20	19.48

The results in table 2 are in terms of total item scores (29 items). In terms of mean item scores the means would be normal group 4.43, patient group 4.86, and delinquent group 3.83. In the patient group there was no statistically significant difference between "line" and "service" troops in terms of total

F Scale score. In none of the groups is there a statistically significant difference between Selective Service and Regular Army troops in total I Scale score.

The distribution of the normal group was relatively symmetrical and somewhat platykurtic. The distribution of the patient scores was markedly skewed, with the low score end of the distribution missing. Distribution of delinquent scores was symmetrical but very platykurtic.

Product moment correlations between total I Scale score and educational level are, for the normal group,  $-0.27$ , for the delinquent group,  $0.03$ , and for the patient group,  $-0.28$ . These correlations are statistically significant in the normal and patient groups. In the normal group, correlation with age is  $0.11$ , with length of service,  $0.15$ , and with rank,  $0.07$ . The correlation with length of service is significant at  $0.05$  level of confidence. Perhaps the most interesting feature of these correlations is not that there are some statistically significant ones, but that the relationships are so very small, in view of what has been written about the relationship of I Scale responses to intelligence, education, status, environmental influence, et cetera.

In general, there is evidence of a definite relationship between authoritarianism as reflected in F-Scale responses, and the type of adjustment manifested by the groups studied, with the greatest difference found between the delinquent and the neurotic types of maladjustment.

The finding of high authoritarian attitudes in the patient group is not an unexpected finding in view of past descriptions of the authoritarian individual as an essentially neurotic person. However, the delinquent group is an equally neurotic group in terms of their inadequate adjustment to the realistic life situation in which they find themselves. Hence there seems to be an attitudinal parallel to the real difference between expressing of tensions in overt antiauthority actions and developing anxiety or psychosomatic symptoms.

One possible clue to this difference is a recent study by Bass,<sup>4</sup> who concluded that acquiescence or compliance accounts in large part for the direction and degree of F Scale responses. If it is true that the F Scale measures compliance rather than authoritarianism, the results obtained in the present study indicate that the normal group is a moderately compliant group, the patient group extremely compliant, and the delinquent group a rather uncompliant one, results which certainly parallel the adjustmental situation. An authoritarian attitude (or compliance) of moderate degree could mean ability to bend with the inescapable wind rather than be broken by it, and could hardly be regarded as neurotic, except where it is overdone or accompanied

by indications of basic conflict (as in the patient group) The results obtained here are consistent with Frenkel Brunswik's<sup>1</sup> discussion of the nonlinear relationships between authoritarian (F scale) attitudes and mental health particularly with respect to the so called principle of opposites

Another aspect of the present study requires discussion because of the considerable evidence that the situation exerts a determining influence on the response to questionnaires The normal group was the only one in which the individuals were absolutely certain of anonymity Since the delinquent individuals were in the highly uncomfortable position of being accused one might expect on this basis alone that they would agree with all items particularly those relating to acceptance of authority for safety's sake The normal group being completely anonymous could criticize authority as much as they liked As a matter of fact all groups were almost identical in agreeing to such items as "Obedience and respect for authority are the most important virtues children should learn" the mean item scores being 6.04 6.12 and 6.91

The differences between groups were found on the less obvious items and therefore it would seem that the lack of anonymity in the two maladjusted groups did not exercise a determining influence in terms merely of an attempt to figure out what the tester wanted or what would "look best" A possible explanation is that the items relating to respecting authority loving one's parents above all et cetera are answered simply as stereotypes by most people with little actual thought because these are conventional and acceptable sentiments whereas on the less reasonable sounding items critical faculties or resistances come into play For example the delinquent group agreed much less than the patient group that one learns only by suffering that people are either weak or strong that our lives are controlled by plots that we must take special precautions against infection by others et cetera Perhaps the patient group members in their efforts to deal with their own disturbing rebellious tendencies simply suspend critical faculties at this "action" level almost completely whereas the delinquent group members mobilize their critical or resistive faculties perhaps too readily on anything not completely congruent with habitual thinking or action

The results obtained in this study have implications not only for medical psychiatric evaluation of maladjusted individuals but suggest a possible line of investigation for military selection Cross validation and replication with other groups is certainly indicated as well as analysis of the aspects of the authoritarian complex which seem to be most relevant to the problem of adjustment to the military situation It is a question as to whether

the authoritarian attitudes are present in the various individuals before entry into military service and hence could furnish a possible clue to their adjustment or maladjustment and to the type of maladjustment, or whether the authoritarian attitudes obtained are themselves developments of more basic and unidentified personality factors and perhaps do not appear until the military experiences mobilize the particular form of adjustment.

### SUMMARY

An exploratory population study on two "maladjusted" groups and one "adjusted" military group was undertaken in order to determine possible relationships between authoritarian attitudes and adjustment in the military situation. California I Scale scores were obtained on a group of delinquent soldiers, a group of psychiatric patient soldiers, and a group of normal, adequately functioning soldiers. Mean scores were significantly different between all groups, the patient group scoring highest, the delinquent group lowest, and the normal group in between. These results are discussed in relation to possible attitudes of compliance or acquiescence and the implications of such attitudes for adjustment, as well as suggesting a line of future investigation with potentiality for use in military selection procedures.

# CASE REPORTS

## Two Unusual Traumatic Dislocations

HAROLD M BRDDEE *Captain USAF (MC)*

**W**ITHIN a brief time interval, both a retrosternal dislocation of the clavicle and a subtalar dislocation of the foot were encountered at this hospital. Each of these interesting traumatic conditions occurs in less than 0.5 per cent of all dislocations.<sup>1,2</sup> This report includes a presentation and discussion of the above mentioned cases.

### CASE REPORTS

**Case 1** On 26 July 1956 a 20 year-old airman was thrown from an automobile and landed on the point of his left shoulder. He felt immediate burning and numbness in the region of the sternoclavicular joint. Shortly thereafter when an attendant inadvertently pulled the patient's left arm to turn him numbness occurred in the left hand. On admission to the hospital a few hours later his left shoulder was held in a shrugged position. Tenderness was present over the sternoclavicular joint area and a depression existed where the prominence of the medial end of the clavicle is normally found. When the shoulder was brought forward he complained of inability to breathe due to pressure on the trachea. Pulses and sensation in the left upper extremity were normal although subjective numbness was present in the hand. Roentgenograms revealed retrosternal displacement of the clavicle (fig. 1). Approximately six hours after the injury closed reduction was attempted under local anesthesia. Twenty milliliters of 1 per cent Xylocaine Hydrochloride (brand of lidocaine hydrochloride) was injected into the dislocation hematoma. With an assistant pulling outward on the arm direct lateral traction was applied to the clavicle by hooking the thumb and index finger about its midportion. The medial end of the clavicle returned to its normal position with a crunch. Roentgenograms revealed satisfactory reduction (fig. 2). A plaster yolk support was maintained for five weeks. The patient was involved in a brawl while on his first week-end pass without recurrence. He was returned to full duty 24 September asymptomatic and with full range of motion at the left shoulder. A check roentgenogram prior to discharge demonstrated normal position of the sternoclavicular joints (fig. 3).

---

From U. S. Air Force Hospital Park Air Force Base, Cliff Dr. Brddee now at 3400 Spruce Street Philadelphia, Pa.

Figure 1 (case 1) Right oblique view of sternoclavicular joints before reduction showing (A) sternal end of left clavicle behind the sternum (B) small oval bony fragment (source not apparent) and (C) sternal end of right clavicle. Figure 2 (case 1) Right oblique view immediately after reduction.

*Figure 3 (case 1) Anteroposterior view of sternoclavicular joints at time of hospital discharge demonstrative normal position of sternal end of clavicles. Small avulsed bony fragment is no longer discernible.*

**Discussion** Stability of the sternoclavicular joint under ordinary circumstances is assured chiefly by the capsular apparatus containing the anterior and posterior sternoclavicular ligaments and the rhomboid (costoclavicular) ligament. The latter particularly limits upward excursion of the sternal end of the clavicle. The tendinous attachments of the sternomastoid in front, the sternohyoid and sternothyroid behind and the subclavius muscle belly below afford additional reinforcement. While suprasternal, presternal and retrosternal dislocations may occur the latter is the least common and potentially the most dangerous.

The dislocation may result from force applied indirectly, as in a fall on the point of the shoulder<sup>1,2</sup> or directly, as from a rule kick<sup>3</sup> or blow from a rifle butt. Experiments on cadavers have demonstrated how the first rib protects against posterior dislocation unless the shoulder has been subjected to severe compression while in the shrugged position. The proximal end of the clavicle is forced down and back until it impinges on the first rib. It is then levered upward and usually forward, rarely backward. The intra-articular meniscus follows the sternal end of the clavicle. A small flake of bone, avulsed from the first rib or sternum may be observed on the roentgenogram.<sup>4</sup>

Clinical recognition of the condition is relatively simple. Severe complications or even death may occur, however, because of accompanying laceration of the great vessels, thoracic duct, trachea, esophagus, or the pleural dome. Open reduction was necessary in all cases found in the literature,<sup>10</sup> and fascial repair<sup>11</sup> or excision of the sternal end of the clavicle was required in most. Closed reduction within six hours and plaster volar fixation for five weeks produced an excellent result for the patient reported herein.

**Case 2** On 29 August 1956 a 17 year old man suffered an injury to his right foot on the basketball court. After jumping to score a basket his right foot struck the upright standard as he descended and he landed on the floor with the foot in an inverted position. Roentgenograms taken immediately demonstrated complete subtalar dislocation of the foot (figs. 4 and 5). Physical examination revealed an extreme inversion

Figures 4 and 5 (case 2) Note complete inversion dislocation at subtalar joint. Talus has remained in its normal position in the ankle mortise.

deformity of the foot. The skin on the lateral aspect was blanched by the pressure of the talus. Sensation and circulation were intact. Under general anesthesia two hours after the injury, the foot was reduced by traction with the knee flexed (fig. 6). Plaster immobilization was maintained for five weeks. The patient was returned to duty without restriction of motion in the foot or a

Figure 3 (case 1) Anteroposterior view of sternoclavicular joints at time of horizontal discharge demonstrating normal position of sternal end of clavicles. Small avulsed bony fragment is no longer discernible.

**Discussion** Stability of the sternoclavicular joint under ordinary circumstances is assured chiefly by the capsular apparatus containing the anterior and posterior sternoclavicular ligaments and the rhomboid (costoclavicular) ligament. The latter particularly limits upward excursion of the sternal end of the clavicle. The tendinous attachments of the sternomastoid in front, the sternohyoid and sternothyroid behind and the subclavius muscle belly below afford additional reinforcement. While suprasternal, presternal and retrosternal dislocations may occur, the latter is the least common and potentially the most dangerous.

The dislocation may result from force applied indirectly as in a fall on the point of the shoulder,<sup>2-6</sup> or directly as from a 'knee kick' or blow from a rifle butt.<sup>7</sup> Experiments on cadavers have demonstrated how the first rib protects against posterior dislocation unless the shoulder has been subjected to severe compression while in the shrug position. The proximal end of the clavicle is forced down and back until it impinges on the first rib. It is then levered upward and usually forward, rarely backward. The intra-articular meniscus follows the sternal end of the clavicle. A small flake of bone avulsed from the first rib or sternum may be observed on the reentgenogram.<sup>7</sup>

Clinical recognition of the condition is relatively simple. Severe complications or even death may occur, however, because of accompanying laceration of the great vessels, thoracic duct, trachea, esophagus, or the pleural dome. Open reduction was necessary in all cases found in the literature,<sup>12</sup> and fascial repair<sup>11</sup> or excision of the sternal end of the clavicle was required in most. Closed reduction within six hours and plaster volk fixation for five weeks produced an excellent result for the patient reported herein.

**Case 2** On 20 August 1956 a 17 year old man suffered an injury to his right foot on the basketball court. After jumping to score a basket his right foot struck the upright standard as he descended and he landed on the floor with the foot in an inverted position. Roentgenograms taken immediately demonstrated complete subtalar dislocation of the foot (figs. 4 and 5). Physical examination revealed an extreme inversion

Figures 4 and 5 (case 2) Note complete inversion dislocation at subtalar joint. Talus has remained in its normal position in the ankle mortise.

deformity of the foot. The skin on the lateral aspect was blanched by the pressure of the talus. Sensation and circulation were intact. Under general anesthesia, two hours after the injury, reduction was easily obtained by traction, plantar flexion, and eversion of the foot with the knee flexed (fig. 6). Plaster immobilization was maintained for four weeks. The patient was returned to duty on 29 October, without a limp or restriction of motion in the foot or ankle.

Figure 6 (case 2) Postreduction roentgenogram with foot encased in plaster

**Discussion** The interosseous talocalcaneal ligament is the chief agent responsible for the integrity of the subtalar joint. It is assisted in this task by the capsular ligaments of the talocalcaneal and the talocalcaneonavicular joints. The latter consists of a number of ligaments continuous at their edges. The lowest fibers of the deltoid ligament close the joint medially; the interosseous talocalcaneal ligament forms the postero-inferior part of the capsule; the lateral calcaneonavicular ligament closes the joint laterally; and the talonavicular ligament forms the upper part of the capsule.<sup>12</sup>

Subtalar dislocations may be inward, outward, backward, or forward. The former is the most common variety and may result from force applied to a foot in the inverted position. The talus is the only bone in the body without muscular attachment<sup>13</sup> and following the dislocation it drops into an equinus position, still well seated in the ankle mortise. Reduction is easily accomplished by reversing the direction of the dislocation with the knee flexed.<sup>14</sup> Prompt reduction and plaster immobilization for three to six weeks leads to an excellent result with little loss of stability or motion.<sup>15</sup> Since the major blood supply to the talus is undisturbed, avascular necrosis is not a problem.

# Actinomycosis of Mandible

HARVEY S JOHNSON *Captain DC USA*  
EDWIN J PULASKI *Lieutenant Colonel MC USA*  
CALVIN F THOMPSON *Captain, DC USA*

**A**CTINOMYCOSIS a granulomatous disease caused by the anaerobic organism *Actinomyces bovis* is not common among military personnel. When it does occur, the clinical form is usually cervicofacial involving the soft tissues. Necrosis of bone as an early manifestation is rare. Nevertheless, the possibility should be considered in the differential diagnosis of all subacute and chronic inflammatory processes of the cranial bones in which the causative agent is obscure. This report describes involvement of the mandible by *A. bovis* and the difficulties encountered in establishing the diagnosis.

## CASE REPORT

A 22 year-old Caucasian soldier was admitted to the Dental Service of this hospital on 31 August 1956 with cellulitis of the mandibular area of the left side of the face. He had been referred from a British military dispensary on a small island in the South Pacific.

The patient first experienced discomfort on 30 June 1956 2 months prior to admission at this hospital while aboard ship en route from London to the South Pacific. During the long cruise he had several episodes of swelling of the left side of the face with mandibular trismus and severe pain. Each time the condition regressed temporarily following penicillin therapy but during an acute exacerbation on 2 August 1956 spontaneous discharge of purulent exudate occurred within the oral cavity at the left buccal sulcus. Upon arrival of the patient at his duty station on 10 August incision and drainage were accomplished and he was observed closely until transferred to this hospital.

Prior to embarking from London the patient had been stationed at a nearby post in the country. He denied that he had chewed leaves, twigs or grass. Pending bacteriologic diagnosis he was given oral hygiene and started on a course of 0.5 gram of erythromycin three times a day.

The patient's temperature was 98.6 F, pulse rate 68/min and respiration 18/min. Physical examination was essentially negative.

except for a hard induration over the left mandibular area moderate trismus exhibited in mandibular movements and a discrete brawny red swelling in the submandibular area inferior to the region of the mental foramen. Introral examination revealed a full complement of caries free teeth. The third molars were impacted. The left second bicuspid had no pulp vitality. The soft tissues of the oral cavity were normal in color and tone, with the exception of the left mandibular buccal sulcus where there was evidence of a recent incision. Pus expressed from this incision was cultured and yielded alpha hemolytic streptococci.

The results of routine blood studies, urinalysis, serologic examinations, and roentgenogram of the chest were normal. A left lateral roentgenogram of the mandible revealed two markedly radiolucent areas both approximately 1.5 by 1.5 cm in size (fig. 1) of which one was near the mental foramen and the other posterior and inferior to the second molar tooth. Irregular margins appeared along the course of the mandibular canal between the two radiolucent areas. A postero-anterior projection revealed a lifting of the periosteum at the inferior border of the mandible.

Figure 1 Roentgenogram showing extensive destruction of left mandible

The day after admission incision and drainage were performed under endotracheal general anesthesia through the erythematous swollen submandibular area. While the heavy beard was being shaved in preparation for the operation the skin was nicked and pus was released. Exploration through the enlarged opening disclosed ruptured, friable grossly necrotic submandibular tissue. Surprisin encountered. Swab cultures from this streptococci and *Micrococcus pyogene*.

### DISCUSSION

Differentiation of actinomycosis from granulomas due to *nocardia*, *coccidioides*, tuberculosis, neoplasms, and syphilis is imperative. Even though fungal infection may be suspected, considerable difficulty may be encountered in validating the suspicion.<sup>1</sup>

Perlstein<sup>2</sup> stated that physical and immunological properties of the original granulomatous tissues and the character of the inoculum determine the distribution, paucity, or absence of the actinomycosis in exudates. As demonstrated in our case, repeated cultures were negative for specific pathogens. Holm<sup>3,4</sup> has advanced the hypothesis that actinomycotic infections are mixed infections which arise through synergism of the anaerobic ray fungi and various pyogenic bacteria. Thus, argument prevails as to whether actinomyces is the true invasive pathogen or a chance contaminant superimposed on a nonspecific infection. The latter thesis is suggested in our case, provided one assumes the precipitating factor to have been pyogenic dental infection with superinfection by *A. bovis*.

Coley<sup>5</sup> and Coley and Higinbotham<sup>6</sup> separated bony actinomycosis into three categories—primary infection, secondary involvement of bone by encroachment from adjacent, soft tissues, and secondary involvement of bone by hematogenous metastatic foci. Our case was not metastatic. Could the infection have been primary or was the osseous infection secondary to soft tissue infection? This question remains unanswered inasmuch as the patient

# Metallic Foreign Body in Mandible for 59 Years

LOUIS J LOSCALZO D D S  
MORTON S BROD D D S

**T**HE presence of a metallic foreign body in human tissues often requires no more than local care of the wound. The foreign body may be permitted to remain in place and merely be noted on a medical chart for future reference, since late reactions to foreign bodies after years of dormancy are no longer considered unusual.

On the other hand, situations will arise when removal of a foreign body metallic or otherwise, becomes prudent or even immediately necessary. It may impinge on essential anatomic structures incite infectious reactions or be a source of continuous pain. Nevertheless, the apparent tendency is to weigh the alternatives carefully before attempting its removal. Antibiotics have notably reduced the incidence of infection, but accurate localization continues to remain a frequent problem. The ease that follows poses no such difficulties.

## CASE REPORT

A 77 year old Negro, a veteran of the Spanish-American War was referred to this hospital for evaluation of a symptomatic foreign body located in the right mandible. The patient gave a clear history of having received gunshot wounds to the face during his military service in 1899 and of being aware for many years that a "bullet" lay lodged in his jaw. Its entrance he described as somewhere at the right angle region though only a suggestion of scarring could be found. His chief complaint of pain on eating and tenderness of the cheek over the mass started several months earlier when the remainder of his teeth on the affected side were removed.

Examination revealed a poorly nourished man in no acute distress. There was a hard mass over the right body of the mandible continuous with it and extending outward raising the thin overlying facial tissues from other normal contour which were very tender to palpation. Intraorally the same mass was located in the mucobuccal fold of the buccal cuspid molar area the overlying mucosa being tender and inflamed.

Radiographs revealed the presence of a large metallic fragment, 1 by 2 cm, embedded in the mandible as described, with multiple, smaller, irregularly shaped, metallic foreign material situated locally (fig. 1). Several small spherical densities also were seen overlying the facial bones and scattered throughout the chest wall.

Figure 1 Roentgenogram showing bullet in right mandible and numerous spherical densities scattered over facial bones.

A thorough medical study was requested. All laboratory tests were within normal limits, and no contraindications to surgery were encountered.

At operation, anesthesia was obtained by local anesthesia and infiltration. A mucoperiosteal flap was reflected. Little resistance, except in the region of the masseter muscle, was encountered in capsular fashion, incorporating elements of the masseter muscle bundle. By sharp and blunt dissection, the bullet was exposed, circumscribed and found to be coming a well-formed bullet, approximately 0.38 caliber. Half of the bullet was removed in an anteroposterior direction and the remaining portion was removed in varying degrees by bone-like tissue (fig. 2). The bullet was removed at the point of the missile was lead-tipped and was of the type which movement could be obtained by elevating a portion of the adjacent bone and the bullet was removed. The bullet was found to be cortical in nature. Several small lead particles were found, some of which were firmly fixed. These, though superficial, were left in place. The wound was debrided of soft tissue and closed with interrupted No. 000 black silk sutures.

#### A CASE OF FACIES RUBER MEDICI

"A 26-year-old patient who had been seen on previous occasions because of corneal scars following trachoma in his childhood, associated with high myopia complained of a burning sensation in his eye.

"He was examined with the slitlamp and the left eye showed numerous dustlike iridescent particles in the anterior chamber and also on the iris surface. The pupil was deep black and did not react to light. The possibility of cholesterol crystals in the anterior chamber was considered.

"During the examination the patient was restless and almost hostile making a more careful observation impossible. Further studies were abandoned when he pointed out that this was his glass eye."

—JOHN J STERN M D  
in *American Journal of Ophthalmology*  
p 308 Feb 1957

with complete cessation of symptoms and on the seventh postoperative day the patient was discharged

*Figure 2 Photograph of bullet showing partial covering of bone*

*Figure 3 Postoperative roentgenogram revealing various lead particles left in situ.*

**Comment** Bullets and other foreign bodies entering bone often do not incite a violent reaction. Usually a capsule of connective tissue is found surrounding the foreign body, and then a layer of sclerotic bone. In some cases, however, the object is in direct contact with bone. It was impressive to note in this case how perfectly the tissues had adapted themselves to the foreign body. There was no evidence whatsoever of any lytic process around the bullet. It is reasonable therefore

to assume that the foreign body was asymptomatic in bone, but that once the thin cheek tissues were no longer supported by tooth, their distention at one point became painful, especially with motion of the jaws

Seldom does one have the experience of removing a bullet that had been in vivo for 59 years

### A MESSAGE FROM THE A M A

One of the many important topics acted on at the 106th Annual Meeting of the American Medical Association in New York City in June 1957 should be of particular interest to all physicians, because it pertains to the ethical conduct of the medical profession. After five years of discussion and deliberation by the governing body of organized medicine, the House of Delegates of the American Medical Association approved a revision of the Principles of Medical Ethics.

In June 1952 recognizing the need for a revision of the Principles of Medical Ethics, the House of Delegates assigned the task to the A M A's Council on Constitution and Bylaws. In December 1953 and during subsequent sessions of the House of Delegates piecemeal revisions were considered. Some of these were adopted while others were referred for additional study. Following these actions, an entirely new proposal for revision of the Principles was submitted to the House in June 1956. It was voted that the new version should lie over until the next meeting of the House before final action would be taken. In December 1956 the House adopted the preamble and 6 of the 10 sections of the new principles as submitted. It recommended that a restudy of sections 6 and 7 should more clearly define the ethical problems of corporate practice of medicine, fee splitting and the dispensing of drugs and appliances. Following this restudy of sections 6 and 7, recommended changes were suggested and accordingly acted on during the June 1957 session of the Association.

The final version presented by the Council on Constitution and Bylaws and then amended by reference committee and House discussion in New York City, is submitted as a matter of interest to military medical officers. The newly adopted principles now read as follows:

#### PREAMBLE

These principles are intended to aid physicians individually and collectively in maintaining a high level of ethical conduct. They are not laws but standards by which a physician may determine the pro-

From the Council on National Defense of the American Medical Association. The views and opinions expressed are not necessarily those of the Department of Defense.  
—Editor

priety of his conduct in his relationship with patients with colleagues, with members of allied professions, and with the public

*Section 1* —The principal objective of the medical profession is to render service to humanity with full respect for the dignity of men. Physicians should merit the confidence of patients entrusted to their care, rendering to each a full measure of service and devotion

*Section 2* —Physicians should strive continually to improve medical knowledge and skill, and should make available to their patients and colleagues the benefits of their professional attainments

*Section 3* —A physician should practice a method of healing founded on a scientific basis and he should not voluntarily associate professionally with anyone who violates this principle

*Section 4* —The medical profession should safeguard the public and itself against physicians deficient in moral character or professional competence. Physicians should observe all laws, uphold the dignity and honor of the profession and accept its self imposed disciplines. They should expose, without hesitation, illegal or unethical conduct of fellow members of the profession

*Section 5* —A physician may choose whom he will serve. In an emergency, however, he should render service to the best of his ability. Having undertaken the care of a patient he may not neglect him and unless he has been discharged he may discontinue his services only after giving adequate notice. He should not solicit patients

*Section 6* —A physician should not dispose of his services under terms or conditions which tend to interfere with or impair the free and complete exercise of his medical judgment and skill or tend to cause a deterioration of the quality of medical care

*Section 7* —In the practice of medicine a physician should limit the source of his professional income to medical services actually rendered by him or under his supervision to his patients. His fee should be commensurate with the services rendered and the patient's ability to pay. He should neither pay nor receive a commission for referral of patients. Drugs, remedies or appliances may be dispensed or supplied by the physician provided it is in the best interests of the patient

*Section 8* —A physician should seek consultation upon request in doubtful or difficult cases or whenever it appears that the quality of medical service may be enhanced thereby

*Section 9* —A physician may not reveal the confidences entrusted to him in the course of medical attendance, or the deficiencies he may observe in the character of patients unless he is required to do so by law or unless it becomes necessary in order to protect the welfare of the individual or of the community

*Section 10* —The honored ideals of the medical profession imply that the responsibilities of the physician extend not only to the individual but also to society where these responsibilities deserve his interest and participation in activities which have the purpose of improving both the health and the well being of the individual and the community

#### CERTIFICATE OF MERIT AWARDED TO NAVY EXHIBIT AT A. M. A MEETING

The scientific exhibit from U S Naval Hospital St Albans N Y on "Newer Approaches to Study of the Liver" was awarded the Certificate of Merit in the Armed Forces section at the American Medical Association meeting held in New York in June 1957. The exhibit which illustrated the joint research work of six or more medical officers portrayed the use of physiologic, histologic, biochemical and isotopic techniques in assessing the liver. Hepatic catheterization was demonstrated by a transparency figure of the thorax with illuminated and animated sequential advance of the catheter through the venous pathways from the arm through the heart to the liver.

## NEW PRESIDENT OF AERO MEDICAL ASSOCIATION

Captain Ashton Graybiel, Medical Corps U S Navy, distinguished teacher and cardiologist, was installed 10 May as the 29th president of the Aero Medical Association at a banquet closing its annual scientific meeting at the Shirley Savoy Hotel in Denver, Colo. He succeeds Dr. Jan H. Tillisch, who is consultant in medicine at the Mayo Clinic and medical director of the Northwest Airlines.

Captain Graybiel has had an illustrious career in aviation medicine. A graduate of Harvard Medical School in 1930, he pursued training in cardiology in Boston, ultimately publishing two volumes on electrocardiography, and is a Past President of the American College of Cardiology. He holds certification by the American Board of Preventive Medicine (Aviation Medicine).

For his contributions to aviation medicine, Captain Graybiel received the Theodore C. Lyster Award in 1950 and the Legion of Merit in 1952. He is at present Director of Research at the U S Naval School of Aviation Medicine, U S Naval Air Station, Pensacola, Fla.

## DISTINGUISHED SERVICE MEDAL AWARDED TO COMMANDING GENERAL OF WALTER REED

The U S Army's highest noncombat award the Distinguished Service Medal was presented on 10 June 1957 to Major General Leonard D Heaton Commanding General of Walter Reed Army Medical Center by

Secretary of the Army Wilber M. Brucker. Those present at the ceremony included Mrs. Heaton, Assistant Secretary of Defense Frank B. Berry and Army Chief of Staff General Maxwell D. Taylor. The citation was as follows:

Major General Heaton distinguished himself by exceptionally meritorious service in a position of great responsibility during the period 9 June 1956 to 15 November 1956. In a number of important surgical operations General Heaton displayed excellent diagnostic acumen, exceptional surgical judgment, outstanding surgical skill and devotion to his patients which resulted in consistently admirable results. His achievements have merited the high regard of his professional associates, exemplified the finest traditions of the service and reflected the highest credit upon himself and the United States Army.

## MEETING OF SECTION ON MILITARY MEDICINE, SCIENTIFIC ASSEMBLY OF A M A

The meeting of the Section on Military Medicine Scientific Assembly of the American Medical Association, which was held in New York in June 1957 during the annual meeting of the Association, was a complete success, with attendance considerably better than it was last year. The professional papers were of high caliber and were followed by authentic discussions that added greatly to the topics presented. The report by Dr Frank B Berry Assistant Secretary of Defense (Health and Medical) relative to the activities of his office during the past year deserves special mention because of its quality and high informative content. The same applies to the paper on "Dependent Medical Care" given by Major General Paul I Robinson MC, USA and discussed by Rear Admiral Nelson Assistant Surgeon General, and Chief of Hospitals U S Public Health Service, and by Captain Guy E. Stahl, MC, USN Director, Dependent's Medical Care Division Bureau of Medicine and Surgery, Department of the Navy.

The following officers were appointed at the business meeting to serve for the 1957-1958 term

Silas B. Hays Major General MC  
USA Surgeon General Department of  
the Army (Chairman)

Alphonse McMahon Rear Admiral MC  
USNR (Ret) Associate Professor of  
Medicine St. Louis University  
School of Medicine St. Louis, Mo  
(Vice Chairman)

Charles H. Branstetter, Colonel USAF (MC) Deputy Director Professional Services Office of the Surgeon General, Department of the Army (Secretary)

Charles L. Leedham, Colonel MC, USA (Ret) Director of Education, Cleveland Clinic Foundation, Cleveland, Ohio (Delegate)

Douglas B. Kendrick, Colonel MC, USA, Office of Surgeon General, Department of the Army (Representative to Scientific Exhibit)

Charles P. Campbell, M.D. of Hackensack, N.J. was re-elected to serve as Alternate Delegate to the Section on Military Medicine.

The officers who served for the 1956-1957 term were Chairman Colonel Russel V. Lee, USAFR (MC) (Inactive), Palo Alto Medical Clinic, Calif.; Vice Chairman Major General Silas B. Hays, MC, USA, Surgeon General, Department of the Army; Secretary Captain Cecil L.

## BOOKS

### Reviews of Recent Books

GIFFORD'S TEXTBOOK OF OPHTHALMOLOGY by Francis Heed Adler  
M D 6th edition 499 pages 227 figures with 26 color plates W B  
Saunders Co Philadelphia Pa 1957 Price \$8

In his preface Dr Adler has emphasized that this book was written for the medical student and general practitioner. This statement has been made by many previous authors but seldom if ever has one succeeded so admirably in producing a text adapted for this purpose. Material of primary interest to the ophthalmologist alone has been deleted.

There are excellent sections on how to examine the eye with the equipment available to the student and practitioner. Other chapters describe what should be looked for and the significance of various conditions. The chapter on disturbances of ocular motility is an extremely valuable one for the practitioner. It points out the causes of various disturbances and their diagnostic significance. It should enable the physician to intelligently refer his patients for care to answer their questions and to actively participate in the treatment

the patients he refers to ophthalmologists. The chapter on refractive errors describing the patient's problems and when he should or should not wear his glasses is lucid. It should help to make the generalist a part of the eye care team and not just a referral agency in it.

The more common eye diseases are detailed and their treatment is indicated. Rarer conditions are omitted. The information given will in most instances enable the physician to determine whether the patient may be safely treated or whether he should be referred to an ophthalmologist for care. The same reasoning has been applied to the material on surgical procedures. Those which a general practitioner may carry out (if properly equipped) are detailed. Other surgical procedures e.g. cataract extraction are explained in principle only but the indications and contraindications for surgery are discussed in detail. The practitioner who has read this section will be in good position to explain why the postoperative cataract patient has certain adjustment difficulties or why certain monocular cataracts should or should not be removed surgically.

The section on ocular manifestations of general diseases emphasizes those diagnostic eye signs which the general practitioner can utilize to diagnose systemic disease. The section on arteriosclerosis and hypertension with the discussion of the fundus findings is alone well worth the price of the book.

There are many new illustrations. They are clear, well reproduced, easily understood, and generous in number.

This book could have been written only by an individual with many years of experience in the teaching of students in ophthalmology. Only such a person could foresee the material which would confuse students and therefore place it in the most understandable form. Only a teacher could have managed to so clearly follow his objective of not writing a condensed ophthalmology book but one devoted to the ophthalmology requirements of a large segment of physicians. This book has been a pleasure to review and it is highly recommended for inclusion in the libraries of medical students and general practitioners of medicine —VICTOR A. BYRNES Brig Gen. USAF (MC)

**THE FIGHT FOR FLUORIDATION** by Donald R. McKay 241 pages Oxford University Press New York N Y, 1957 Price \$5

This excellent little book is written in an interesting style by a qualified historian.

It contains 10 very well documented chapters covering the years 1901-1956 beginning with the original work of McKay and carrying through some of the most recent referenda.

The writer employs many quotations and anecdotes in giving a blow by blow description of the fight for adoption of one of the most controversial public health measures of our time. The cautious attitude of the researchers, the exuberant enthusiasm of the profluoridation clinicians, and the "rabble rousing" tactics of their opponents are vividly recounted.

The story unfolds as would a historical novel. Each chapter reveals a new facet of a real life struggle that could occur only in America. The issue of human welfare versus human rights arises at every turn.

The volume closes with two valuable sections, one a 28-page outline of notes containing all references by chapter and the other containing an essay on the sources of this material.

This work will find many readers, especially those interested in dental history, and those in the field of Public Health Dentistry.

—DONALD C. HUDSON Col USAF (DC)

**CLINICAL OPERATIVE DENTISTRY**, edited by William John Simon. 381 pages 650 illustrations on 538 figures. W. B. Saunders Co., Philadelphia, Pa., 1956 Price \$9.50

Clinical operative dentistry has never been recognized as a separate field of study in dentistry. As pointed out by Dr. Simon, the majority of textbooks on operative dentistry in the past have included other fields. However, in the progress of recent years these have been segmented out as specialized areas of study.

Dental caries has often been recognized as the most endemic of human disease. Therefore, its prevention and control is of vital im-

portance to the health of all mankind. This excellent publication deals in its entirety with the science of the treatment of dental caries, embracing most of the known tried and accepted techniques as well as new developments in the art of operative dentistry.

An excellent and complete evaluation is made of the various types of cavity preparation required for each of the accepted filling materials used in dental restorations. In addition the clinical indications for each type of material are clearly and logically defined. Dr. Simon comprehensively but without too much detail discloses the basic physical properties of each filling material. This provides the student or the practitioner with the knowledge to select a proper filling material for the tooth at hand.

Not only are the basic fundamentals of cavity preparation clearly described for each material but identification to meet variations in stress and retention are also well portrayed. Step-by-step procedures from the initial cuts in the preparation to the final polishing of the filling are clearly and completely described. Many ingenious techniques described in the placement of silicate and acrylic materials cannot only be applied as timesavers for the practitioner but will prove to be valuable knowledge to the student.

The contents of the chapter Inlay Restorations with its excellent illustrations and clear description of the various techniques of inlay construction should provide a source of valuable comprehensive knowledge to all practitioners who are interested in maintaining and reviewing their inlay capabilities.

The chapter on the use of gold foil is also complete and comprehensive. For the practitioner who only on occasion avails himself of the use of this king of all filling materials this chapter would afford an invaluable review of cavity preparation and handling of gold foil. The use of the rubber dam with its unparalleled ability to provide a sterile and dry field of operation and many other advantages is well covered.

Although this book appears to be primarily designed as a textbook of clinical operative dentistry for students it should be well received by those members of the profession whose practice for the greater part embraces the dental operative fields. It will provide material for review and improvement of professional competence since it not only includes tested and tried techniques but also covers fully the latest advancements that have proved practical and sound.

—CHARLES S. O'GRADY, Col. USAF (DC)

August 1957)

REVIEWS OF RECENT BOOKS

1239

THE EARLY DETECTION AND PREVENTION OF DISEASE edited by John P. Hubbard M D 350 pages The Blakiston Division, McGraw Hill Book Co Inc, New York N Y 1957 Price \$7.50

One of the major problems yet to be solved in public health lies in the field of early detection and prevention of disease. This book is a timely and important contribution to the solution of a major public health problem. The prevention of many noncommunicable and chronic diseases and/or their disabling effects lies within the province of the practitioner of medicine. The subjects covered include preventive medicine in relation to the cardiovascular system, the gastrointestinal system, the musculoskeletal system, pelvic cancer, mental health and a review of immunization and the practical application of preventive medicine in the armed services. It is regrettable that more was not said about mental disorders and alcoholism, as well as neoplasia.

This volume is an edited symposium, by many authors at a five day meeting arranged and directed by the Department of Public Health and Preventive Medicine, University of Pennsylvania. The intent was to develop a better understanding of preventive medicine in the clinical practice of medicine. It represents independent and separate thinking by outstanding men in each field on the early detection and prevention of disease.

This publication is recommended for all persons interested in the practice of medicine and should be of great value to the practicing physician and public health leaders.

The material in regard to each subject is short and would perhaps leave much to be desired from individuals seeking specific knowledge. The bibliography following the subjects is adequate. It is hoped that this type of work will create an interest in additional publications. Unfortunately, the lack of much factual data and the brevity of many of the subjects with an excessive price, will perhaps considerably reduce the sale of this important publication.

—THOMAS G. FAISON Col MC, USA

SPINAL CORD COMPRESSION Mechanism of Paralysis and Treatment by I. M. Tarlov M D 147 pages illustrated Charles C Thomas Publisher Springfield Ill, 1957 Price \$7.50

In this book for the first time a program is presented for the treatment of patients suffering from spinal compression syndromes. This program is based on controlled animal experiments and supported by careful studies in man. The author is Professor of Neurology and Neurosurgery at New York Medical College and is well known for his attempts to blend together experimental studies and clinical facts.

The book is divided into three sections. The first is on experimental studies—an introduction. A simple, unique method of studying spinal compression under carefully regulated conditions is presented in detail. Physiologic and histologic results are discussed. The second section

is on clinical studies. Here a review of literature is given with a discussion of spinal cord and cauda equina compression by trauma and tumors. The results of decompressions and a guide to prognosis for the patient is given. The third section is on early management of acute compressive spinal paralysis. The mechanisms of injury, the first aid and the indications for and the timing of operation is shown.

The author has presented in this compact but comprehensive monograph a logical approach to the problem, that tremendously important problem found in the patient with impending or already complete spinal cord paralysis. The illustrations are good. The language and terminology is clear and simple. The book is intended as a guide and inspiration for further work and is a sensible approach in the management of those so afflicted. —FRANK B. CLARE, *Corvallis, OR, USA*

**BASIC FACTS OF PHARMACOLOGY** by Stewart W. Brooks. Pp. G. B. S. M. S. 323 pages illustrated. W. B. Saunders Co. Philadelphia Pa. 1957. Price \$4.

This new text written especially for the student nurse has definite value for all nursing service personnel who have responsibility for the administration of drugs and direct patient-care.

The author has used an unique approach in stressing the actions of drugs. The core of the textual material is concerned with the actions of drugs (facts which do not change). Basic drugs are simply and completely discussed in relation to their respective actions on the central nervous system, the autonomic nervous system, the heart, blood vessels, and blood and body surfaces. Drugs used to treat infections are described as "anti-infectives" and are classified as local and systemic anti-infectives.

Meaningful illustrations serve to provide a knowledge of the relationship between the chemical composition and the pharmacologic actions of the drugs covered in the text. Structural chemical formulas used in the form of illustrations are self-explanatory and contribute to the basic intent of the author.

A separate chapter is devoted to a discussion of hormone therapy. Further drugs which do not logically fall in the separately discussed classes are treated as "miscellaneous agents."

The subject of toxicology is discussed specifically in relation to general principles of treatment and a comprehensive classification of poisons is presented.

Pertinent questions are included at the end of each chapter. The appendix contains a complete glossary of all terms used in the text, a list of important drugs in current use, and suggested experiments for use in demonstrating specific types of pharmacologic action.

August 1957)

REVIEWS OF RECENT BOOKS

1211

The unique format and style of this text should have special appeal to its users. Professional and nonprofessional nursing service personnel as well as instructors in nursing should derive great benefit from this essential ready reference. —DOROTHY V. ELLIOTT May ANG

ANNALS OF THE NEW YORK ACADEMY OF SCIENCES Volume 66, Part 3  
Pages 417-840 March 14, 1957 Editor-in-Chief Otto V. St. Whitelock  
Associate Editor Franklin A. Furness "The Pharmacology of Psychotomimetic and Psychotherapeutic Drugs" Conference Chairman and Consulting Editor Seymour S. Kety 423 pages illustrated The New York Academy of Sciences New York N.Y. 1957 Price \$5

This volume is a compilation of papers presented at a conference on psychotomimetic (phrenotropic) and psychotherapeutic (ataractic) drugs sponsored by the New York Academy of Sciences in April 1956. The goal of the conference was to present a summary of the current hypotheses concerning the neurophysiologic action, biochemical activity, and pharmacologic and clinical effects of phrenotropic and ataractic drugs in present-day experimental and clinical use.

There is an additional series of papers presenting several hypotheses as to the role of the substance serotonin in the central nervous system.

This compilation is highly technical in nature, but will be of great value to the scientist interested in basic clinical research into the activities of these drugs and their relationship to the mechanisms of cerebration. The practicing clinical psychiatrist should find much value in the material presented regarding the biochemical and pharmacologic basis for the clinical action of these drugs in mental illness, as well as for their side effects.

As a matter of general medical interest there appears a rather sobering series of hypotheses which should be carefully considered in view of the present day wide and sometime indiscriminate use of ataractic drugs, that their action might represent a basic effect on the molecular structure of cerebral cells that they may be drastically altering the cellular and enzymatic systems concerned in the transmission of cerebral synaptic impulses or may be exerting a mass effect on the mechanical actions of glial cells in brain nutrition.

A great deal of organizational effort is apparent in the presentation of differing hypotheses with regard to the specific action of each of these drug groups and the discussion sections of the papers present material in support and refutation of their hypothesis as well as material additionally presented in an effort to gather together information from all the hypotheses in order to provide valid paths for future research. There are interesting historical sidelights on the development of understanding of the chemical dynamics of the central nervous system and a few papers detailing the general or chemical activity of phrenotropic and ataractic drugs used since antiquity such as mescaline, rauwolfia, and ibogaine.

Included in each section are some philosophical ponderings regarding the general effects of these drugs on civilization with one especially interesting premise that perhaps basic research on these drugs might now provide a bridge between *Homo faber* and *Homo sapiens* the advent of an era of transition in medical research from the mechanics of human behavior to the philosophy of human behavior.

—DEAN J. PLAZA, U. MC, USA

**HUMAN CANCER** A Manual for Students and Physicians by Maurice A. Black, M. D. and Francis D. Sree, M. D. F. C. A. P. 273 pages illustrated. The Year Book Publishers Inc. Chicago Ill. 1957. Price \$7.50.

This is an effort to present the experimental biologic biochemical clinical and therapeutic aspects of human cancer in a 273 page volume. The aim of the authors is "a concise and systematic presentation to guide the neophyte to what is known indicate the unknown and controversial orient him toward critical observations and the contributions of new knowledge" in human cancer. The authors accomplish this aim well with the medical student always in mind.

That both of the authors are pathologists could be suspected from the excellence of the chapters on human carcinogenesis and biological behavior of cancer. Similarly their laboratory orientation is demonstrated in the clinical chapters where the selection of sources and the bibliography are not always the most authoritative. Also characteristic of many pathologists is their lack of enthusiasm for cytological diagnostic methods and procedures radical surgery and excessive palliative measures in cancer.

This book should be an excellent text for cancer co-ordination courses in oncology in medical schools.

—RONALD A. GRANT Capt MC USA

**COLD INJURY** Transactions of the Fourth Conference November 7, 8 and 9 1955 Princeton N. J. edited by A. Irene Ferrer M. D. 371 pages illustrated. Josiah Macy Jr. Foundation Publications New York N. Y. 1956. Price \$5.95.

This volume follows the same format of informal discussion by experts as previous Transactions of Conferences on Cold Injury sponsored by the Josiah Macy Jr. Foundation. Though the Medical Director of these Conference Groups Dr. Frank Fremont Smith, frankly states in the foreword that such a format has aroused some criticism along with considerable interest much can be said in favor of it particularly the lively candid and constructive criticism and exchange of ideas by the various distinguished participating scientists (17 members and 12 guests).

The rapidly increasing importance of local and general cold injury is clearly set forth in the diversified subjects discussed. Detailed

August 1957)

REVIEWS OF RECENT BOOKS

1217

clinical and experimental data and opinions on frostbite—at times rather controversial—are presented in the first eight chapters, stimulated largely by experiences in World War II and the Korean conflict.

The last four chapters appear to this reviewer as even more timely and provocative: Resuscitation of Hypothermic Supercooled and Frozen Mammals; Blockade Techniques as Protective Measures Against Ventricular Fibrillation During Hypothermia; Clinical Application of Hypothermia During Open Heart Surgery and Cerebral Studies During Local and General Hypothermia. The vital implications of these basic and clinical researches are obvious in the light of recent rapid advances in cardiac surgery and prospective advances in neurosurgery.

The only criticism of this book is considered to be the delay in its publication since this Fourth Conference on Cold Injury was held in November 1955 whereas recent newspaper reports have already appeared on the Fifth Conference on Cold Injury held near Fairbanks, Alaska.

This volume is especially recommended to interested physiologists and pathologists for the experimental designs described and results achieved as well as to the cardiologist and thoracic surgeon for a view of the careful basic work required for the expanding horizons in this field. —H. LEONARD JONES Capt. MC USA

THE YEAR BOOK OF RADIOLOGY (1956-1957 Year Book Series) Radiologic Diagnosis, edited by John Floyd Holt M.D., and Fred Jenner Hodges M.D. Radiation Therapy, edited by Harold W. Jacox M.D. and Merton M. Kligerman M.D. 430 pages illustrated. The Year Book Publishers, Inc. Chicago Ill. 1957. Price \$9.

This is a well organized book of abstracts of important articles in radiology selected from American and foreign journals published between June 1955 and June 1956. The reviews are concise, clearly stated and excellent summaries of pertinent information contained in the originals.

The first section of the book deals with diagnostic and therapeutic radiological advances and the second with radiologic therapy. This latter part includes some interesting articles on hazards of radiation and radiobiology, which has been so well publicized in the lay press recently. The articles in both sections are presented in a logical, orderly fashion by systems such as head and neck, chest, gastrointestinal tract, spine and extremities and genitourinary tract. This makes it easy to locate articles on a particular system.

This excellent book is a must for radiologists as a source of ready reference. The specialist in other fields would do well to review the articles that are related to his particular specialty.

—JAMES M. KEEGAN Maj. USAF (MC)

**DISCUSSIONS ON CHILD DEVELOPMENT** *A Consideration of the Biological Psychological and Cultural Approaches to the Understanding Of Human Development and Behaviour* edited by J. M. Tanner M D Ph D D P M and Barbel Inhelder Volume I The Proceedings of the First Meeting of the World Health Organization Study Group on the Psychobiological Development of the Child Geneva 1953 240 pages illustrated Volume II The Proceedings of the Second Meeting of the World Health Organization Study Group on the Psychobiological Development of the Child London 1954 270 pages illustrated International Universities Press Inc New York N Y 1957 Price \$10 for set of two volumes

The Mental Health program of the World Health Organization (WHO) was started in 1949 and since that time there has been much effort on the part of the Expert Committee on Mental Health in the Direction of survey co ordination and stimulation of research In 1953 the WHO Study Group on the psychobiological development of the child met in Geneva for a week In 1954 the Study Group met for a week in London Their assignment was to discuss the influence of psychological biological and cultural factors in human development and the approaches to these factors for further understanding

Dr Frank Fremont Smith presided at the meetings with Dr G R Hargreaves acting as secretary The proceedings were recorded and later edited The Study Group at both sessions was distinguished international and interdisciplinary in composition John Bowlby in psychoanalysis Jean Piaget Barbel Inhelder and René Zazzo in psychology J M Tanner in human biology Margaret Mead in anthropology Konrad Lorenz in ethology W Grey Walter A Rémond Marcel Monnier and K A Melin in electrophysiology and R R Struthers in research promotion By bringing this group together it was hoped that an opportunity would be provided for the development of mutual understanding between workers in different disciplines and that out of increased understanding would come jointly undertaken research and increased effort to relate the findings of one discipline to those of another Prepared presentations were kept short and were used mainly to stimulate discussions in a particular area In this way the emphasis was placed much more on the listener and his contribution than on the presenting person The discussion was free rapid shifting and wide ranging

Volume I (1953 meeting) The major areas for discussion at this meeting were the physical and physiological aspects of child development Piaget's concepts of the levels of mental development Wallon's descriptions of motor development in early childhood electroencephalographic development of children psychological development of the child psychoanalytic theory and ethology and cross cultural studies as they pertain to the personality development

Volume II (1954 meeting) The discussion in this meeting related to learning theory learning under stress and learning in an immature

## KNOWLEDGE—LOOSE TALK

You as doctors are frequently called upon by your patients in casual conversation and with lawyers to express thoughtful and helpful opinions. The accomplishment of this in both a responsive and responsible manner requires general knowledge in broad education, an inquisitive mind, willingness to continue to develop your own intellectual catholicity, and the avoidance of garrulousness. This becomes increasingly important with the increasing development and use of radioactive substances.

For example

(1) A man working in one of the large centers developed infectious mononucleosis. A doctor was called upon to explain this and to back up the contention of the wife that this could be caused by radiation. He was confronted with all sorts of clippings from popular magazines and news papers.

(2) The second case is that of the baby born with cleft palate. The parents immediately propounded the same question to the doctor.

In both instances the doctors did not have self assurance in their own knowledge to state definitely that both of these conditions were common even long before the days of radiation exposure. These examples illustrate the danger of wishing to place the blame for ordinary conditions on radiation, one as to causation of radiation illness and the other as to its effect upon genetics.

Knowledge will bring assurance to the physician and reassurance to his patient. Conversation, loose talk and uncritical opinions will spread alarm and anxiety and eventually will cause trouble for both the physician and his patient.

## Foreword

The United States Armed Forces Medical Journal is the medium for disseminating information of administrative and professional interest to all medical personnel of the Department of Defense. The Assistant Secretary of Defense (Health and Medical) and the Surgeons General of the several services invite all medical officers dental officers Medical Service Corps officers Nurse Corps officers and officers of the Veterinary Corps of the Armed Forces and the medical consultants of the Army Navy and Air Force to submit manuscripts for publication in this Journal.

## HISTAMINERGIC NERVE EFFECTS IN RELATION TO PEPTIC ULCER

*Preliminary Experiments on Dogs*

PETER H. BULLE, M.D.  
MARGARET A. AVERY, M.S.

**E**MOTIONAL stress is known to induce certain somatic changes that may be related to hyperactivity of the sympathetic nervous system.<sup>1-3</sup> In the normal individual, such sympathetic stimulation causes reduction of gastric acid formation or of gastrointestinal motility.<sup>4,5</sup> Clinical observation shows that the peptic ulcer patient under emotional stress experiences an aggravation of his symptoms, usually accompanied by excessive secretion of hydrochloric acid (HCl).<sup>2,6</sup> This difference of organ reaction to sympathetic stimulation in the peptic ulcer patient leads us to assume the existence of a constitutional abnormality in his sympathetic nervous system.<sup>7,8</sup> It is the purpose of this study to elucidate the nature of this abnormal predisposition. Our approach to this problem was based on a number of recent findings:

1. Sympathetic nerve structures were found to contain not only adrenergic, but also histaminergic fibers in varying proportions. The existence of such histaminergic fibers was established with the finding that histamine is present in<sup>9-12</sup> and capable of stimulating<sup>10-13</sup> sympathetic nerves and, conversely, that nerve stimulation leads to peripheral histamine release.<sup>14,15</sup>

From Department of Pharmacology, Georgetown University Medical School, Washington, D. C.

2 Evidence was adduced to show that psychogenic factors may lead to central stimulation of the histaminergic fibers<sup>15</sup>

3 It was found that central stimulation of histaminergic fibers may result also from parenteral administration of histamine<sup>16</sup>

These findings in conjunction with the long established fact that histamine is a powerful stimulant of gastric acid secretion,<sup>17-19</sup> prompted us to investigate the mechanism by which histamine causes gastric hyperacidity

### MATERIALS AND METHODS

For each series of experiments, mongrel dogs weighing about 10 kg were used. HCl secretion in response to intravenously administered histamine phosphate (10 gamma/kg) was measured by sampling gastric juice immediately before and 15 and 60 minutes after the histamine administration. Maximum secretion of HCl should have occurred 15 minutes after the injection of histamine, whereas the effect should have largely disappeared after 60 minutes. Because both free and bound HCl had to be determined individually on the samples, the results are recorded separately in the tables.

The specimens were collected by oral insertion of a rubber tube into the stomach of the experimental animals. Twenty five milliliters of water was injected via this tube and the stomach contents were withdrawn 2 to 3 minutes later. The dogs had received no solid food for 12 hours prior to the procedure. During the testing period they were given only the measured quantities of water by gastric tube. This unvarying procedure was followed with the controls and after (a) sectioning of the cervical spinal cord below the 5th or 6th vertebra, (b) intravenous administration of hexamethonium (10 mg/kg), (c) intravenous administration of chlorpromazine (0.5 mg/kg), and (d) intravenous administration of amphetamino sulfate (0.2 mg/kg). Sectioning of the cervical spinal cord was performed using Pentothal anesthesia and attempts to obtain a histamine response were made 1 hr after the administration of Pentothal Sodium (brand of thiopental sodium).

### RESULTS

On the assumption that in the dog as in man there are constitutional variations in sensitivity to histamine, 12 dogs were tested in a preliminary control series by the procedure outlined above. Only five responded with strong acid secretion of the gastric glands. Detailed findings on these five are shown in table 1. The other seven dogs failed to respond to either 100 gamma or 5 000 gamma of histamine. Accordingly in subsequent series only dogs with demonstrated ability to respond to histamine were used.

Sectioning of the cervical spinal cord abolished the histamine response (table 2). The autonomic ganglionic blockade induced by hexamethonium had the same effect, lasting for 4 to 8 hr (table 3). Chlorpromazine effectively inhibited the histamine response for the duration of 5 to 7 hr (table 4). Amphetamine prevented the histamine effect upon gastric acid secretion for 5 to 7 hr in 5 out of 6 dogs (table 5).

### DISCUSSION

The dogs were accustomed to intubation in order to alleviate their apprehension to this procedure. To obtain relative values for the gastric acidity of the experimental animals, it was necessary to inject a constant amount of water into the stomach, as this organ in the resting state does not contain gastric juice in quantities sufficient for sampling. The cervical spinal cord was severed to obtain complete interruption of all preganglionic sympathetic fibers. Care was taken to leave the phrenic nerves intact. Diaphragmatic breathing was found sufficient for the maintenance of adequate oxygenation. The dogs were anesthetized with Pentothal Sodium, because this ultrashort acting barbiturate in the dosage used does not interfere with impulse transmission through autonomic ganglia. One hour was allowed to elapse between the surgical and the testing procedures to preclude experimental errors from possible effects of the anesthetic or trummitization.

Our experimental finding that surgical interruption or pharmacologic blockade of impulse transmission through the sympathetic nervous system abolished the histamine effect on the gastric glands indicates (a) that the centrally originating sympathetic structures which innervate the stomach contain histaminergic fibers and (b) that these fibers conduct the central impulses to the stomach. The phenomenon that in the normal individual stimulation of the sympathetic nervous system (through emotional stress) leads to an adrenergic response (reduction of gastric acidity or motility) seems to indicate that, normally, the adrenergic fibers predominate over the histaminergic fibers. As the peptic ulcer patient responds to emotional stress with an overproduction of HCl (a histaminergic reaction), it may be assumed that in his case the histaminergic fibers prevail in the sympathetic structures innervating the stomach. It is suggested that this particular anomaly represents a constitutional predisposition which plays a role in peptic ulcer formation. Two factors have to concur in the development of the disease, the constitutional and the psychogenic. Consequently, treatment of peptic ulcer may be approached in two ways, (a) by removing emotional stress, and (b) by correcting the histaminergic predominance.

To test the efficacy of drugs that could be expected to control the neural imbalance the action of hexamethonium, chlorpromazine, and amphetamine (all neurotropic agents) upon gastric acid secretion was studied. The hexamethonium effect on the histamine induced HCl response may be attributed to its sympathetic, rather than its parasympathetic, blocking property, as atropine (a parasympathetic inhibitor) is known not to inter-

fered with that histamine action<sup>20-22</sup>. Hexamethonium as a non specific autonomic ganglionic blocking agent, seems to be of limited therapeutic value however it should be useful, together with atropine as a diagnostic aid for the differentiation between histaminergic hyperacidity and cholinergic (food related) acidity. The finding that chlorpromazine prevented the histamine induced

gastric acid secretion indicates that this agent is capable of inhibiting central histamine effects, a property which apparently is not shared by other synthetic antihistaminics<sup>20, 21-25</sup>. The drug seems particularly suited for the treatment of peptic ulcer, because as a tranquilizing agent it has the additional advantage of

tion of its usefulness as a therapeutic agent in peptic ulcer particularly as it is known to have potent mood elevating properties and thus may alleviate the emotional stress as well

SUMMARY

... provokes gastric acid secretion ... the histamine

## SUMMARY

**SUMMARY**

The mechanism by which histamine provokes gastric acid secretion was studied in the dog. It was found that the histamine induced gastric acid response can be abolished (a) by sectioning of the preganglionic sympathetic fibers and (b) by autonomic ganglionic blockade with hexamethonium. It was postulated that the sympathetic structures innervating the stomach carry histaminergic as well as adrenergic fibers and that the constitutional predisposition for peptic ulcer consists in a predominance of the histaminergic fibers. Based on clinical evidence it was concluded that for the development of the disease in man a psychogenic factor has to concur with the constitutional anomaly. Chlorpromazine and amphetamine were tested and found to effectively control histaminergic acid formation. Their possible therapeutic indication was discussed.

tion of its usefulness as a therapeutic agent in peptic ulcer, particularly, as it is known to have potent mood elevating properties and thus may alleviate the emotional stress as well

# SUMMARY

The mechanism by which histamine provokes gastric acid secretion was studied in the dog. It was found that the histamine induced gastric acid response can be abolished (a) by sectioning of the preganglionic sympathetic fibers and (b) by autonomic ganglionic blockade with hexamethonium. It was postulated that the sympathetic structures innervating the stomach carry histaminergic as well as adrenergic fibers and that the constitutional predisposition for peptic ulcer consists in a predominance of the histaminergic fibers. Based on clinical evidence, it was concluded that for the development of the disease in man a psychogenic factor has to concur with the constitutional anomaly. Chlorpromazine and amphetamine were tested and found to effectively control histaminergic acid formation. Their possible therapeutic indication was discussed.

ACKNOWLEDGMENT The authors are grateful to John A. Jereb and Lawrence F. Sanctilio for their technical assistance

patients requiring Wangersteen suction, chest drainage, or tracheotomy care are kept on the special care ward as long as need for this care exists. Those with head injuries and other serious injuries are immediately put on the special care ward where observation, maintenance of an airway, et cetera, can be carried out properly. Fluid intake and output, state of consciousness, blood pressure, temperature, pulse, respiration, and other observations are recorded on the patient's chart at the foot of the bed, where they are freely accessible at all times.

The special care ward is headed by a well qualified surgeon who is responsible for all patients. The anesthesiologist sees all postoperative patients and supervises postanesthetic care, ward surgeons from other wards are encouraged to see and follow their cases, each surgeon writes his own postoperative orders, and patients who have been operated on because of orthopedic, urologic, eye, ear, nose, throat, or gynecologic conditions are treated by the respective services, but it is essential that one surgeon have over all responsibility for the ward.

During the past year, about 1,000 acutely or seriously ill and 4,000 postoperative patients have benefited by the facilities of the special care ward at this hospital. During the same period, approximately 400 patients with head injuries, 200 in traumatic shock, 8 with severe gastrointestinal bleeding, and 20 with severe burns were admitted directly to the ward. About 30 tracheotomies were performed on patients with head injuries and severe maxillofacial and cervical trauma. Emergency artificial respiration with intratracheal intubation was carried out on 5 patients. Intravenous cutdowns for polyethylene tubing were done in many cases. Emergency chest drainage was carried out 24 times in patients with traumatic or spontaneous pneumothorax. Immediate aftercare of two patients who received massage for cardiac arrest was accomplished, with survival of both.

Because of the increasing shortage of nurses, all wards can not be completely staffed by nurses, especially at night. By concentrating those patients needing a great amount of nursing care on one ward, as was proposed by Beardsley, Bowen, and Capalbo,<sup>1</sup> isolated patients requiring such care are brought where they can get it. Due to early ambulation, within 24 hours unless contraindicated for a specific reason, patients usually are at least partially ambulant when sent to their own wards, and can assist in their own care. Dressings are removed from most non-drained wounds after 24 hours. This makes for drier, less irritated wounds, better wound observation, better patient minimized dressing procedures on other wards.

Advantages of the special care ward include

1 Expert professional care, as well as special equipment and knowledge of its use are always immediately available to those who need them

2 Close observation of the critically ill surgical patient and recording of important facts are reliably carried out

3 Danger that a remote case might be neglected as a result of shortage of professional help is obviated

4 Professional help may be safely spread thinner on other wards

5 Need for special nurses or attendants for the individual patient is obviated

A separate anesthesia recovery ward is desirable in large hospitals if staffing is possible while the combined type of ward is recommended for the average hospital where expert and adequate staffing of every ward is out of the question. I am convinced that the facilities of our special care ward have saved many lives, prevented many complications, saved the time of professional personnel and contributed to the smooth and uneventful recovery of the average surgical patient.

# NONTUBERCULOUS CHEST CASES ORIGINALLY DIAGNOSED AS TUBERCULOUS

## A Five Year Study

JAMES M SCHLESS M D  
JAMES A WIER Colonel MC USA

**B**URKE AND WIER<sup>1</sup> reviewed the nontuberculous cases originally admitted to the tuberculosis service at this hospital in the years 1952 through 1954 and compared this study with similar observations made at another institution some years previously.<sup>2</sup> Their original series of cases has been expanded and brought up to date, so that our present series now covers dispositions from this hospital for the period 1952 through 1956. Insofar as possible, the cases included in the earlier series have been reviewed and certain minor alterations made so that the criteria used in compiling the figures for 1952 through 1954 are the same as those used for 1955 and 1956.

The current discussion is limited to patients in whom a chest abnormality was demonstrated roentgenographically, or in whom other evidence pointed to a chest lesion that was originally diagnosed as either definitely or possibly tuberculous and for which the patient was admitted to the tuberculosis service upon his arrival at this hospital. Certain cases in which the patients had normal chest roentgenograms are included in this study. These mainly fall into the "no pulmonary disease found" final diagnosis group, and include errors in roentgenographic interpretation as well as a fairly good sized group in whom positive bacteriologic findings were reported without any evidence of pulmonary disease. This group will be discussed at greater length farther on in this article.

Exclusive attention will be paid to those conditions that tend to be confused with pulmonary tuberculosis. No consideration will be given to other significant conditions such as diabetes, orthopedic conditions, arteriosclerosis, psychiatric disturbances, and gastrointestinal diseases, which, in some instances, were much more bothersome to both the patient and to the physician than a questionable chest lesion that ultimately proved to be nontuberculous.

<sup>1</sup>From Fitzsimons Army Hospital, Denver, Colo.

note, however, that there has been a steady decline in the percentage of such admissions over each of the five years, starting with 17.7 per cent in 1952 and ending with 13.2 per cent in 1956. This would reflect an over-all increase in diagnostic acumen on the part of the referring physicians and probably indicates better and more complete initial study of patients with chest diseases. There seems to be an increasing awareness of non-tuberculous chest diseases, accompanied by a decreasing inclination to call any obscure chest lesion tuberculosis.

Table 2 shows the final diagnoses in order of frequency in the 851 patients originally admitted to the tuberculosis service who had ultimate nontuberculous diagnoses at discharge. It will

TABLE 2 *Fifteen leading nontuberculous chest diseases in order of frequency originally diagnosed as tuberculosis 1952-1956*

Disease	Number of patients	Per cent

No pulmonary disease	95	11.0
Undiagnosed lesions	16	1.9
Grand total	851	100.0

be noted that these 15 conditions account for over three fourths (76.3 per cent) of the entire series. An additional 11 per cent had no pulmonary disease. In 1.9 per cent, no satisfactory diagnosis was ever established, but these cases were presumed to be nontuberculous. The remaining 10.8 per cent, consisting of 91 cases, were divided among 33 other conditions. These were extremely interesting as including infrequently encountered conditions that they do not

trends. Because space will not permit elaboration on every category of diagnosis, these 91 cases will be passed over with no more mention than notation in the tabulation of discharge diagnoses (table 3)

Most of the remaining part of this article will be devoted to a detailed analysis of the 15 most common discharge diagnoses and the group in whom no pulmonary disease was confirmed. Together, these two categories account for 744 out of our 851 cases, or 87.3 per cent of the series. Individual categories of discharge diagnosis will be discussed in order of frequency of the top 15 conditions over the five year period followed by discussion of the "no pulmonary disease" group.

### PULMONARY FIBROSIS AND/OR CALCIFICATION CAUSE UNDETERMINED

Pulmonary fibrosis and/or calcification cause undetermined, is admittedly a wastebasket diagnosis in which 126 cases (14.8 per cent) are included. For the most part these patients showed localized fibrosis with stable lesions, often demonstrable over long periods. These lesions were usually considered clinically insignificant and not of an extent to justify biopsy. Cultures for *Mycobacterium tuberculosis* were obtained routinely and were negative at this installation although some of these patients were originally admitted with a report of a single positive smear or culture which was unconfirmed and considered erroneous in the light of subsequent study. Many of these persons had negative tuberculin skin tests. The importance of tuberculin testing and the "false positive" bacteriologic tests will be discussed in greater length later in this article.

There is no doubt but that some of the lesions included in this group really represent clinically insignificant healed minimal tuberculosis residuals.

It is significant to note the steady decline in the frequency of this diagnosis. In 1952 40 out of 233 cases, or 17.5 per cent, were given this final diagnosis. In 1956 only 6.6 per cent, or 8 out of 121 cases, ended up in this category. This trend can probably be explained by one or more of the following factors: (1) improved diagnostic techniques, (2) willingness to make a diagnosis of fungus infections especially histoplasmosis on the basis of history, roentgenographic appearance and skin and serologic tests without confirmation by surgery, (3) increasing awareness of other conditions such as pulmonary infarction that can produce pulmonary fibrosis and (4) the policy, during the period of this study, of routinely returning military personnel with inactive tuberculosis to a duty status.

At the present time we have no great hesitancy about making a diagnosis of minimal inactive tuberculosis and clearing the

patient for continued duty, whereas formerly such a diagnosis might have unjustly interfered with a man's career and future. In such cases, in earlier years, the inclination would have been to give the man the benefit of the doubt and make some other diagnosis, such as pulmonary fibrosis, because clinically significant tuberculosis could not be proved.

### PNEUMONIA

Pneumonia proved to be the cause of pulmonary lesions in 10.3 per cent of our cases. The range has been 14.6 per cent in 1952, 12.4 per cent in 1955, and 7.4 per cent in both 1953 and 1956. Thus, we have no consistent trend over the past five years. These variations probably depend on the incidences of respiratory infections year by year and locality by locality. It is to be noted that upper lobe pneumonias, especially those of the viral type, can mimic the roentgenographic findings of tuberculosis. It may take many weeks or even a few months to clear a pneumonic infiltration completely. Occasionally, false positive sputum cultures are obtained or transiently positive ones develop as a result of inflammatory erosion of an old tuberculous focus into a bronchus. When such a situation arises, it is easy to see how legitimate confusion can result. Friedländer pneumonia can look like an acute caseous pneumonic process, even showing cavitation on the roentgenogram. *Klebsiella pneumoniae* may easily be missed in the sputum unless specifically suspected and looked for.

Pneumonias not infrequently show uneventful resolution, leaving pseudocavities which may be radiologically indistinguishable from tuberculosis on conventional roentgenograms. Undoubtedly, there will always be a certain residual of cases in which the differential diagnosis cannot be made in a reasonable time with the facilities available at the installation originally seeing the patient. In such a case, an initial admission diagnosis of possible tuberculosis will probably remain justified.

If certain points are remembered, however, some unnecessary diagnoses of tuberculosis, with the attendant trauma and anxiety that this diagnosis always brings, can be eliminated.

- 1 Every infiltration in the upper lobe is not necessarily caused by tuberculosis.
- 2 A reasonable period of observation under appropriate non-tuberculous chemotherapy will frequently give many answers.
- 3 A negative tuberculin skin test adequately done with freshly prepared PPD and repeated on several occasions will, for all practical purposes, exclude the diagnosis of tuberculosis.
- 4 A patient with an acute tuberculous pneumonic process will usually have sputum which is strongly positive for *Mycobacterium tuberculosis*.

tuberculosis. Adequately examined and cultured sputum specimens which are repeatedly negative would argue very strongly against a diagnosis of tuberculosis.

5 In some instances, the more uncommon pneumonias, such as Friedlander pneumonia, should be borne in mind.

### HISTOPLASMOSIS

The diagnosis of histoplasmosis is being made with increasing frequency. The five year average has been 9.3 per cent, in 1956. For the year 1953 to 1956, histoplasmosis held first place in the list of final diagnoses of nontuberculous patients admitted to the tuberculosis service as definite or possible tuberculosis. The chances are that it will remain near the top of the list until awareness of the great differential diagnostic importance of histoplasmosis is a matter of common knowledge.

In early years, biopsy, positive fungus cultures, or high serologic titers were considered necessary to establish this diagnosis. Today we are making the diagnosis more and more on the basis of history, positive skin tests, and roentgenographic findings, especially if the tuberculin is negative.

Coin lesions with definite "target" calcifications or diffusely scattered fine pulmonary calcifications are characteristic of histoplasmosis and in the presence of a positive skin test we are inclined to make this diagnosis without biopsy. We believe that the histoplasmin skin test is very specific for this disease. However, we believe that it is very important that the same syringe is never used for both tuberculin and histoplasmin, inasmuch as residual contamination can produce false positives in either direction. Occasional cross reactions with coccidioidin and blastomycin have been observed.

There is no doubt that in the past many patients were given treatment for tuberculosis when, in reality, they had histoplasmosis. Many of the large number of pulmonary fibrosis and/or calcification, cause undetermined cases of the earlier years would probably be considered as histoplasmosis today. However, roentgenographic findings are not typical and in whom the tuberculin and/or coccidioidin as well as the histoplasmin skin tests are positive.

There will always be patients who have round foci without calcification but who have a positive reaction to the histoplasmin skin test and no documentation as to how long the lesion might have existed. In these cases, of course, thoracotomy for diagnostic purposes continues to be indicated to establish a differential diagnosis between tuberculosis tumors histoplasmosis,

or other diseases caused by fungi. An occasional case will prove to be histoplasmosis in the presence of a negative reaction to histoplasmin. Therefore, unlike the tuberculin skin test, a negative reaction to the histoplasmin skin test does not exclude histoplasmosis with certainty.

### BRONCHIECTASIS

The trend has been a decrease, year by year, in the number of cases of bronchiectasis misdiagnosed as tuberculosis. Certain factors probably explain the increasing frequency of bronchiectasis as a primary diagnosis and, therefore, the decreasing frequency of original misdiagnosis.

1 Awareness that this condition may occur in the upper lobe as cystic bronchiectasis, probably on a congenital basis, or that it may be present as a result of an old or recent bronchoocclusive lesion followed by infection. The roentgenographic findings in such cases can frequently be confused with those in tuberculosis.

2 More routine use of careful skin testing.

3 Awareness of bronchiectasis as a common cause of hemoptysis.

4 More careful history and physical examination, especially the observation of an area of persistent localized rales.

5 Increased routine use of bronchoscopy and bronchography.

Even after taking all of the above factors into consideration, there may be many times when the differential diagnosis is difficult from a roentgenographic point of view. In such cases, the presence of a positive tuberculin skin test and/or a false positive sputum or gastric culture will lead to a very legitimate presumption of tuberculosis.

Thus, we believe that a certain number of patients with bronchiectasis will probably continue to be admitted with their disease diagnosed as possible tuberculosis, no matter how careful the original studies. Careful attention to the various factors outlined above should keep the incidence of this particular diagnostic error to a minimum.

### COCCIDIOIDOMYCOSIS

The number of cases of coccidioidomycosis originally considered as tuberculosis dropped sharply after 1952. Some of this may be due to improved primary diagnosis of coccidioidomycosis. Other cases undoubtedly were included in the "undetermined" group.

Because coccidioidomycosis frequently causes pulmonary lesions, it may easily be confused with tuberculosis.

nection, it is wise to remember that the coecidioidomycosis cavity frequently, though not invariably, tends to be thin walled and that pericavitary reaction is usually much less marked than in tuberculosis. However, coecidioidomycosis can produce in filtrations which roentgenographically are indistinguishable from tuberculosis, and visa versa.

In this disease, the skin test is not as specific as in either histoplasmosis or in tuberculosis. There is a sizable percentage of patients eventually proved to have coecidioidomycosis who have negative skin tests, at least in the usual 1:100 dilution, although some of these will be positive at 1:10 dilution. A patient with a reaction negative to coecidioidin and positive to tuberculin, and with roentgenographic findings compatible as tuberculosis, will, therefore, continue to be considered as tuberculosis on initial evaluation. Even if the reaction to coecidioidin is positive, if the reaction to tuberculin is also positive, and the roentgenographic findings could be compatible with either, there is a legitimate reason to consider tuberculosis until proved otherwise.

The following considerations might help to reduce the incidence of erroneous diagnosis of tuberculosis in cases of coecidioidomycosis.

- 1 The endemic areas comprise a large part of the Southwestern United States. Thus, not only is this disease endemic in the San Joaquin Valley, but also in large parts of southern California, Arizona, New Mexico, and West Texas. Many military and Air Force personnel are stationed in this endemic area and will give a history of having been stationed there at some time in their career. In virtually every proven case of coecidioidomycosis a history of having at least visited in an endemic area can be obtained.

- 2 The coecidioidin skin test, although imperfect, should be routinely used as this will point the finger of suspicion at a majority of cases and at least indicate this condition as a definite diagnostic possibility.

- 3 Serologic studies and complete physical examinations should be done in all suspicious cases. There may be a normal titer found either in the very early acute case or in the old case with chronic residuals. Serial agglutination studies are often important and significant serial changes in titer may be diagnostic in suspected lesions.

- 4 Sputum and/or gastric specimens may often be positive for *Coccidioides immitis* especially in cavitary cases. Fungus cultures and mouse inoculations should therefore be done in all suspected cases.

5 Any cavity lesion which fails to reveal *Mycobacterium tuberculosis* on repeated examinations, should make one suspicious that the disease might be something other than tuberculosis

6 Diagnostic thoracenteses will continue to be necessary in a fair number of cases *C. immitis* spherules should be routinely looked for in all resected granulomatous lesions

### PIEURISY

The diagnosis of tuberculous pleural effusion admittedly is usually inexact. In most cases, no pulmonary infiltration is ever found and no bacteriologic proof is ever obtained. Because of the high relapse rate in untreated tuberculous effusion, and the fact that significant pulmonary disease almost never develops following adequate chemotherapy of a tuberculous effusion, one would much rather treat some patients unnecessarily than overlook any significant cases.

*Primary pleural effusion* of unknown cause in patients who have a positive reaction to tuberculin, either on admission or after several weeks of observation, is presumed to be tuberculous. These patients are given a course of chemotherapy.

Most patients not fitting the above criteria can be eliminated prior to transfer to a tuberculosis center if careful attention is paid to the following: (1) *Primary* meninges without other apparent cause. Acute respiratory infections, especially pneumonia, may produce pleural effusions. Pulmonary emboli, tumors, tracheitis, and virus infections are some of the other conditions which cause pleural effusions. Every effort should be made to establish a definitive diagnosis in all cases, if possible. This should include thoracentesis during the acute phase with careful bacteriologic and cytologic examination of fluid. (2) *Effusion* meninges that the patient has fluid. Occasionally an effusion may develop which is evanescent, showing complete clearing after a few days or a couple of weeks. This is distinctly unusual behavior for an untreated tuberculous effusion and should arouse suspicion as to some other cause. Each year, we see a number of patients in whom there is no effusion but evidence of old pleural thickening with obliteration of a costophrenic sulcus. In most of these patients, old roentgenograms are eventually obtained which show this to be a remote process and an old and unchanging lesion. A little thought and patience in obtaining old films would eliminate most of these cases. (3) If a patient with a pleural effusion is negative to freshly prepared PPD, and if he remains negative after 60 to 90 days on repeat test, tuberculosis can be eliminated as a cause of the effusion.

## GRANULOMA CAUSE UNDETERMINED

Some of these cases represent patients in whom it was believed that tumor was excluded clinically and tuberculin tests excluded on the basis of persistently negative tuberculin tests but in whom both coccidioidin and histoplasmin were positive and therefore, no clinical differential diagnosis could be made. Thoracotomy was not believed to be indicated in some of the patients because of the limited extent of the lesion and the proven stability of the process. In others, thoracotomy was advised for diagnosis but refused by the patient.

In many of these cases, however, surgery was performed and no definitive diagnosis was made. It is interesting to note that in 1952 there was no case in which a final diagnosis of granuloma was made. A relatively high incidence was found in 1953 and in 1955. A lower incidence of this diagnosis was obtained in 1954 and 1956. These wide swings are probably, in part at least, explained on a local situation at this hospital and could be ascribed to personnel changes in the pathology and bacteriology departments and individual differences in willingness to commit oneself to a positive diagnosis if any element of doubt exists.

All granulomas should be diligently examined by tissue sections with appropriate staining as well as by smear and by cultures for both fungi and *Mycobacterium tuberculosis*. In spite of the painstaking investigation, the pathologist is bound to run across an occasional case in which he simply cannot make an etiologic diagnosis. The fact that no such case was found in 1952 seems to be either sheer good luck or an exceptional degree of skill on the part of the pathologist or maybe a little of both. On the other hand the 14 cases so diagnosed in 1955 might signify a run of difficult cases, unwillingness on the part of the pathologist to commit himself if he had the least doubt, or a deficiency in technique.

Probably the 1954 and 1956 figures represent the usual betting average for this diagnosis.

## SARCROIDOSIS

The discharge diagnosis of sarcoidosis is being made with generally increasing frequency in the last three years as compared with the first two years of this study again probably because of an increasing awareness of its existence and the increasing use of surgical biopsy including diagnostic thoracotomy in suspected tuberculous cases and in suspected mediastinal tumor masses.

Sarcoid is often said to be predominantly a disease of the Negro although it is not infrequent in Caucasians. Nodular lung lesions and bilateral hilar adenopathy are the most common thoracic

manifestations. Pulmonary infiltrations tend to be diffuse, linear, and nodular in nature and can be roentgenographically confused with miliary or other extensive forms of pulmonary tuberculosis, tumors, or lymphomas.

Most often the patient is not as clinically ill as his roentgenogram might suggest. The shadows on the roentgenogram are frequently evanescent and can show rapid spontaneous clearing, or increase with no apparent cause.

Great caution should be exercised in making this diagnosis in the presence of a positive tuberculin test, although a negative test is not a prerequisite and many of our patients have shown a positive reaction to tuberculin. In these cases, the diagnosis was made on clinical and roentgenographic grounds, the course of the patient, and most importantly on the basis of repeated biopsies.

It is admittedly possible that the final diagnosis may eventually prove to have been in error and that some of those may actually represent forms of tuberculosis or fungus disease.

Biopsy should be done in all suspected cases, and the diagnosis of sarcoidosis probably should never be made in the absence of positive biopsy findings, because the differential diagnostic possibilities, of both tuberculous and nontuberculous conditions, are usually too serious to permit error.

With the possible exception of the inguinal nodes, any enlarged peripheral node should be removed for biopsy. If there is no peripheral adenopathy, a suprascapular fat pad biopsy should be done as this is a fertile field for finding positive diagnostic tissue. If neither of the preceding gives the answers, a diagnostic thoracotomy with lung or mediastinal node biopsy should be done. The risk of this procedure is small and certainly much less than the risk of overlooking a much more serious disease.

The characteristic pathologic finding is a noncaseating granuloma. If caseation and necrosis are found, considerable doubt is thrown on the validity of a diagnosis of sarcoidosis. Of course, appropriate studies should be done on all biopsy material to rule out possible tuberculous or fungus infection.

Most of the above mentioned studies usually can be carried out at the institution originally seeing the patient, and if awareness of pulmonary sarcoid is high, it should be possible to reduce the incidence of sarcoid cases hospitalized with the diagnosis of tuberculosis or, indeed, called tumor or lymphoma on the basis of an original examination.

#### NEOPLASM OF LUNG PRIMARY

It is noteworthy that the category neoplasm of lung, primary, holds ninth place in the five year total of lesions originally.

considered as tuberculous. Partially, this may be due to the generally younger age group encountered in the military so that, in general incidence in the armed services as a whole is probably less than in the adult civilian populations. To a great extent, however the relatively low place on the list must be due to an increased awareness of the common occurrence of lung tumors on the part of the profession in general. Exploratory thoracotomy is being performed promptly in suspicious cases, especially in lesions in the 40-year and over age groups.

We occasionally encounter tumors however which roentgenographically so closely resemble tuberculosis that a certain error in primary diagnosis will continue to occur. At times, a tumor may erode an old tuberculous focus and produce a misleadingly positive bacteriologic test. Some tumors may cavitate in these instances. Absence of readily demonstrable positive sputum should cause suspicion that the lesion is something other than tuberculous. Uncalcified round foci that are not documented as having been present over a long period of time should all be surgically removed. If a tumor is beyond the limits of bronchosopic visibility and if no ulceration into the bronchial system has occurred bronchoscopy and cytology of bronchial washings will be negative even in highly malignant lesions. Therefore negative bronchoscopy and bronchial washings for tumor cells do not exclude the possibility of tumor although those studies are indicated in all suspicious lesions.

Supraclavicular fat-pad biopsy is useful if extension beyond the lung has occurred. In most cases however exploratory thoracotomy remains necessary to prove or disprove the possibility of neoplasm. A continued high level of suspicion with early exploration in any case where the possibility of tumor is even seriously considered will help to raise the gloomy salvage statistics in cancer of the lung.

In suspicious cases where tuberculosis is also a good differential possibility the patient can be given a short course of intensive antituberculous chemotherapy for a period of from 10 days to 3 weeks prior to thoracotomy.

### BRONCHITIS

Each year a few patients with acute or chronic bronchitis are admitted as possibly having tuberculosis. Persistent coughing, sputum and even hemoptysis might be the reason for suspecting tuberculosis. Frequently a false positive sputum is noted leading to admission. Roentgenographic findings are indefinite and usually no more than increased markings or peribronchial fibrosis is noted. Severe symptoms without definite roentgenographic changes should make one more suspicious of bronchitis or bronchiectasis than of pulmonary tuberculosis. Adequate work

up, including bronchoscopy, bronchography when indicated, and careful and complete evaluation should be done in all cases

### ABSCESS OF LUNG

The few cases of abscess of the lung confused with tuberculosis can be practically eliminated by careful history taking, especially if recent evidence of pneumonitis or aspiration is looked for. Careful physical examination, including observations regarding fever, systemic manifestations, and the type and amount of sputum, must be carried out. The roentgenogram usually shows a cavity lesion, which may be thin or very thick walled. Usually there is less pericavitary infiltration in abscess of the lung than in tuberculosis. Sputum should be cultured routinely and carefully for pathogens as well as for *Mycobacterium tuberculosis* and fungi. A cavity lesion with copious sputum in which acid fast bacilli are not readily demonstrable should cause early suspicion that the patient has something other than tuberculosis, and further study should elicit the proper diagnosis.

### EMPHYSEMA, PULMONARY

Pulmonary emphysema is occasionally confused with tuberculosis, especially localized obstructive emphysema with blebs suspicious of cavitation. The roentgenographic findings are usually somewhat different from those in tuberculosis, although in some patients associated fibrosis may make the differential diagnosis very difficult. Adequate roentgenographic studies, including careful fluoroscopy for evidence of obstructive phenomena, and tomography are useful in differentiating these conditions. Of course, tuberculin testing and careful bacteriologic studies should be done in all cases in which tuberculosis enters into the differential diagnosis.

Pulmonary function studies at times may be quite helpful.

### PULMONARY EMBOLISM WITH INFARCTION

Pulmonary embolism with infarction has been diagnosed with increasing frequency in recent years in patients admitted supposedly as having tuberculosis. This would seem to indicate increasing awareness of this condition by the personnel on the pulmonary disease service at this hospital. Careful attention to the history and careful examination, especially of the legs, for any evidences of thrombophlebitis are important. A history of acute onset with sudden chest pain and cough, with or without hemoptysis, should make one suspicious. Characteristic roentgenographic findings with wedge shaped infiltrations resolving rapidly without definite treatment would point to this diagnosis.

Acute pleural effusion, especially if bloody, which comes on suddenly and clears rapidly is more suggestive of pulmonary embolus than tuberculosis. More critical evaluation of the patient

and more careful follow up for evidences of rapid clearing of suspected lesions should hold this source of misdiagnosis to a bare minimum

### PNEUMOTHORAX SPONTANEOUS

A few cases of spontaneous pneumothorax are seen each year as possible tuberculosis. The older teaching was that tuberculosis was a common cause of this condition, but current information shows that rupture of subpleural emphysematous blebs having nothing to do with tuberculosis is the cause in the great majority of cases. Only a very rare case is the result of tuberculosis. Frequently fluid is apparent after a spontaneous pneumothorax. This may be either bloody or serous depending on how much hemorrhage there has been into the pleural cavity. This is not a primary effusion and if documented as having its onset during or following a spontaneous pneumothorax, the presumption of tuberculosis does not exist even should the patient have a positive tuberculin test.

### HEMOPTYSIS CAUSE UNDETERMINED

"All that spits blood is not tuberculosis." This "wastebasket" diagnosis covers those few cases in which after tuberculosis and other conditions such as tumors, bronchiectasis, bronchitis, heart disease, vascular anomaly, local upper respiratory lesions, pulmonary infarction et cetera, have been excluded, we are left with no good explanation as to why the patient has had a hemoptysis. Most of these cases are legitimately admitted as suspected of having tuberculosis and the final diagnosis represents the culmination of complete painstaking and thorough unrewarding work up. This diagnostic category proves that there are some cases which remain "essential," "idiopathic," "primary," "agnogenic" in plain English. We just have no idea what caused them.

### MISCELLANEOUS CATEGORIES

Having thus disposed of 76.3 per cent of our series, we dismiss another 10.8 per cent with the observation that they comprise 33 separate categories of some individually very interesting cases. But since we must draw the line somewhere, we shall make no mention of them other than listing them in table 3. Another 1.9 per cent can be disposed of by mentioning the 16 cases of "undiagnosed lesion." These patients almost to a man were disposed of by early transfer or were veterans who left against medical advice before adequate diagnostic studies were carried out. The best conclusion was that they were probably nontuberculous; thus they have been included in this series with full realization that we could have included some tuberculosis cases.

## NO PULMONARY DISEASE FOUND

We now come to the final 95 cases. They represent a very disturbing 11 per cent of our patients in whom no tuberculosis was found and who eventually were diagnosed as having no type of pulmonary disease. A few words of explanation regarding the local policy at this hospital are in order to clarify something of what at first appears to be an appallingly large group of cases.

This hospital is not only a large general hospital serving a widespread military and Air Force population and their dependents, but is also a major pulmonary disease, and especially, a major tuberculosis center. A policy has gradually been built up which is somewhat the reverse of that found in almost any other large hospital, military or civilian.

Ordinarily, cases for study and work up without a definitive diagnosis, whether received by transfer or admitted directly from our own outpatient clinics, tend to be admitted to the tuberculosis service if by any stretch of the imagination tuberculosis seriously enters into the differential diagnosis. In most other hospitals, a great number of these patients would probably be admitted to the general medical wards and only transferred to the tuberculosis service if some positive evidence of tuberculosis was found. Thus, undoubtedly, some of the 95 patients in whom no pulmonary disease was found and, indeed, some patients from the previously discussed categories, would originally have landed on the general medical service rather than on the tuberculosis service had they been sent anywhere but to this hospital. Having thus explained away some of our "no pulmonary disease found" as a mirage, we are still left with a substantial number who were needlessly diagnosed as tuberculous and admitted to a tuberculosis hospital. Most of these cases represent avoidable errors. When we consider the severe psychic trauma to the individuals concerned, the interference with a man's career, the unnecessary family inconvenience, the large costs to the Government involved in sending a man half way around the world (in many instances with his family and his furnishings), the unnecessary time lost by a possible essential man on an essential job at an essential time, we can readily see that the error is a costly one, often with far greater implications than a simple mistake in medical judgment.

What then can be done to reduce this source of error? Most of the answers have already been indicated in earlier sections of this article. Thoughtful consideration and attention to detail should be given in all cases. A few specific points are summarized below.

**Tuberculin Testing** This should be done in all suspected cases. As the percentage of tuberculin reactors in our population drops, the tuberculin test is becoming an ever increasingly important pro-

cedure A negative test with freshly prepared intermediate and second strength PPD excludes tuberculosis except in overwhelming infections or early in the course of primary infections The overwhelming infection is usually obvious even without the tuberculin If the tuberculin test does not convert within six to eight weeks after the onset of the disease, the chances are almost 100 per cent that tuberculosis can be excluded

**The False Positive Sputum or Gastric Concentrate** Many of the patients eventually cleared as having no pulmonary disease are admitted because of a single positive laboratory report on sputum or gastric contents with no other evidence to support a diagnosis of tuberculosis Smears of gastric concentrate are a frequent source of error since acid fast saprophytes, morphologically indistinguishable from *Mycobacterium tuberculosis*, are frequently found in smears of stomach aspirates

We believe that smears of gastric concentrates are so frequently misleading that we do not even run them or report them at this hospital Instead, we wait for culture results which, with newer techniques, can be obtained in a relatively short time

Sputum smears are also open to errors of interpretation A trained technician who is thoroughly familiar with the morphologic characteristics of acid fast bacilli is required to correctly interpret the sputum concentrate At times, small scratches in the slide can pick up the acid fast stain, or imperfect staining techniques may result in what are apparently acid fast bacilli but in reality represent foreign material At times though rarely acid fast organisms other than *Mycobacterium tuberculosis* might be found in the sputum A positive smear of either sputum or gastric contents if confirmed by culture, should be suspect

Cultures also may be misleading because certain atypical, acid fast organisms or nonpathogenic contaminants occasionally grow on culture media If the culture is reported as positive in too short a time for the technic used, serious doubt should be entertained that the growth observed actually is *Mycobacterium tuberculosis* The possibility always exists of laboratory errors such as mislabeling of specimens although with painstaking techniques errors can be kept to a minimum In spite of this however, it always is possible in a very busy laboratory that a positive result might be reported when it actually represents a specimen obtained from another patient

A single unexplained positive finding by smear, culture, or guinea pig inoculation that does not fit with the clinical situation is always open to a certain question of accuracy If repeated examinations fail to confirm this single finding, further suspicion arises as to the validity of the single positive report Thus a say that good judgment must be exercised and that under certain

circumstances we are justified in eliminating a positive bacteriologic report on good clinical grounds

**Accurate Interpretation of Roentgenograms** While it is most important that we do not miss significant abnormalities, which unfortunately are too often overlooked, we must also be careful not to grossly overread the roentgenograms. In suspicious cases, repeat roentgenograms with additional views such as apical lordotics, obliques, laterals, and tomography should be obtained to confirm or better delineate a suspected lesion.

**Fluoroscopy** is also very useful in localizing suspected abnormalities. A diligent search should be made in all suspicious cases for old films. In the military, at least a roentgenogram made at the time of induction usually is available. Comparison of serial films often is a vital factor in making a diagnosis.

**Bronchoscopy** In many cases, bronchoscopy is important to prove or disprove endobronchial disease. This is a simple and readily available procedure which can be performed in most military hospitals. At the time of bronchoscopy, bronchial washings for tuberculosis, fungi, and tumor cells can easily be obtained.

**Bronchography** This often is a very important diagnostic tool. In the past, there has been some hesitation in using this modality because Lipiodol (brand of iodized oil) shadows obscured the evolution of serial roentgenographic findings for some time. Today we have good water soluble media which are readily eliminated and will give excellent pictures without interfering with future roentgenographic studies. In indicated cases, therefore, this procedure should be done with no hesitancy.

**Diagnostic Biopsy** Diagnostic biopsy of available nodes, or diagnostic thoracotomy, is necessary at times and should be done wherever needed. If performed by a competent surgeon, the risk is small and frequently is much less than the risk of not doing the biopsy. If tuberculosis is suspected, a short period of intensive antituberculosis therapy prior to biopsy should eliminate the danger of postoperative tuberculous complications.

All the above points are helpful hints that will save unnecessary diagnosis of tuberculosis as well as help in making the correct primary diagnosis, or permit clearance if no disease is found. However, none of the above amount to anything if we forget the basic fundamentals of good clinical medicine, namely, a careful, thorough, and painstaking history and physical examination, critical evaluation of all data, both clinical and laboratory, a high index of suspicion, a searching mind, unsatisfied by a loose or incomplete explanation, good fundamental knowledge of diagnosis and differential diagnosis, and, most important of all, just plain good common sense.

## SUMMARY

Out of a total of 5 324 patients admitted to the tuberculosis service of this hospital with a diagnosis of tuberculosis or possible tuberculosis during the years 1952 through 1956, 851 (16 per cent) were found not to have significant tuberculosis. There has been a heartening decline year by year in this group which speaks well for improved diagnostic and differential diagnostic techniques in chest diseases.

Fifteen nontuberculous conditions accounted for 649 (76.3 per cent) of our cases. These 15 conditions are discussed in some detail. Final clearance with diagnosis of "no pulmonary disease found" was given in 95 (11 per cent) of our cases.

### AMERICAN COLLEGE OF SURGEONS MEETING TO BE HELD IN ATLANTIC CITY

The 43d Clinical Congress of the American College of Surgeons will be held at Convention Hall in Atlantic City N J from 14 to 18 October 1957. Panel discussions will be a major feature of both the general sessions and sessions concerned with the specialties of Gynecology and Obstetrics. Neurologic Surgery Orthopedic Surgery Plastic Surgery Thoracic Surgery and Urology. Closed circuit operative telecasts film lectures and medical motion pictures will popular items as will be the Forum on Fundamental Surgical Problems. This year eight postgraduate courses also will be given. The detailed program may be seen in current issues of *Surgery Gynecology Obstetrics*.

# STUDY OF 507 PATIENTS DISCHARGED FROM A TUBERCULOSIS SERVICE

A Year's Experience at a Naval Hospital

JOHN A C GRAY, *Captain MC USN*  
GEORGE L. SPENCER *Commander MC USNR*

THE TUBERCULOSIS service at this hospital is maintained for the reception, diagnosis, treatment, and disposition of military patients referred because of known or suspected tuberculosis. More than 500 patients are processed annually. In the belief that they may be of interest to others, data are reported on 507 patients who were discharged between 1 October 1955 and 30 September 1956.

Of the 507 patients, 481 (94.7 per cent) were members of the U. S. Armed Forces on active duty. Twenty-six (5.3 per cent) were supernumerary patients. These included 1 member of a foreign navy, 1 civilian evacuated from overseas, 13 retired members of the U. S. Navy, and 11 dependents of military personnel, including 2 children, who were sent in from overseas or admitted in emergency circumstances.

Of the 481 military patients, 24 (4.9 per cent) were officers and 457 (95.1 per cent) were enlisted personnel, 211 (43.8 per cent) were from the U. S. Navy, 39 (8.2 per cent) from the U. S. Marine Corps, 210 (43.6 per cent) from the U. S. Air Force, and 21 (4.4 per cent) from the U. S. Army. Most of the military patients were Caucasian males in their early twenties (table 1).

## DIAGNOSTIC PROCEDURES

Diagnostic procedures on admission included routine immunologic, bacteriologic, and roentgenographic examinations, conducted in an admitting unit under the supervision of a medical officer and the nursing supervisor.

Immunologic studies consisted of intradermal tests performed regularly by a single experienced hospital corpsman, using tuberculin (0.00002 or 0.0001 mg of purified protein derivative), coccidioidin (1:1,000 or 1:100), and histoplasmin (1:1,000 or

1 100) Patients who failed to react to the smaller doses were retested with the larger Old tuberculin (1 100) was employed in doubtful cases The syringes used for each antigen were kept segregated

TABLE 1 Race sex and age of military patients on active duty

	Number	Percent
Race	409	85.1
Caucasian	65	13.5
Negro	2	0.4
Mongolian	4	0.8
Malayan	1	0.2
American Indian		
Sex	473	98.3
Male	8	1.7
Female		
Age in years	61	12.2
17-19	703	42.2
20-24	96	19.9
25-29	84	17.5
30-39	37	8.2
Over 40		

Inasmuch as the Navy has practiced tuberculin testing of Navy and Marine Corps recruits since 1949 the tuberculin reaction of sailors and marines at the time of their enlistment is shown on their records. This information provided an important diagnostic point of reference.

Sputum specimens when available were examined by smear and culture. Where sputum was not available at least three specimens of gastric contents from the fasting patient were inoculated on culture media. Bacteriologic work was conducted by full time personnel in a laboratory built especially for mycology and tuberculosis bacteriology and equipped with maximum safety features to protect the workers' Roentgenograms of the patients' chests were made and compared with those that usually accompanied them.

Bronchoscopy was abandoned as a routine procedure in 1954 after an analysis of 247 consecutive cases showed that routine bronchoscopy produced positive findings in only 22 (8.5 per cent) of the cases. This small harvest did not appear to justify the anesthetic risk to the patients, the direct exposure of personnel to infectious material or the labor involved. Bronchoscopy was of course performed when indicated.

To reduce the length of hospital stay, loss of treatment time, and patient demoralization, every effort was made in each case to reach a diagnosis within 10 days. The patient was then brought before a treatment conference, told his diagnosis, prospective treatment, and disposition, and invited to ask questions. When it proved impossible to establish a diagnosis within 10 days, the reasons for delay were clearly explained.

All patients except eight were tested with tuberculin. Of the eight, five were transferred at once to the surgical service where the admission diagnosis was established by the pathologist, in the other three, the diagnosis of tuberculosis was already abundantly proved, so that the test was superfluous.

Some of the results of the diagnostic procedures are of particular interest. Five patients with tuberculosis were "bacteriologically positive" but "tuberculin negative." One of these was anergic because of acutely disseminated disease and one, who had primary tuberculosis, was assumed to have delayed reactivity. Technical errors probably were responsible for failure to obtain positive tuberculin reactions in the remaining three cases.

Bacteriologic proof of tuberculosis, either from records accompanying the patients or from our own studies, was obtained in 214 (72.1 per cent) of the 308 military patients with active pulmonary tuberculosis. The chief reason for this small percentage was the large number of patients who had only minimal infection that had been detected by routine roentgenography. The percentage of positive bacteriologic findings was 42.7 per cent in cases classed as "minimal," 82.1 per cent in the "moderately advanced" cases, and 92.6 per cent in the "far advanced." Against this background, it was diagnostically reassuring to find that among the 66 Navy and Marine Corps patients under the age of 25, whose reaction to tuberculin at the time of their enlistment was known, it was possible to demonstrate "Mantoux conversion" in 51 (77.1 per cent). Tuberculin negativity is so characteristic of young Americans<sup>1</sup> that a reaction to tuberculin is significant, and "Mantoux conversion" practically diagnostic.

Of the Navy and Marine Corps patients hospitalized with tuberculosis, 22.9 per cent had had a positive reaction to tuberculin at the time of their enlistment, whereas only 4.6 per cent of recruits in general have a positive reaction.<sup>2</sup> This marked difference suggests that a positive reaction to tuberculin is a liability to a young man or woman.

Among the 39 patients with tuberculous pleurisy, bacteriologic proof was obtained in only 5 (12.8 per cent). Many of these pa-

tients had been tapped and drained prior to admission here and consequently offered no fluid for study. Seventeen of these patients were members of the Navy or Marine Corps, and 16 of the 17 were demonstrated to be recent "Mantoux converters." This is additional evidence supporting the view that a young American with an idiopathic pleural effusion who has a positive reaction to tuberculin had best be treated for tuberculosis.

Testing with histoplasmin and coccidioidin resulted in other noteworthy findings. Among 466 patients tested with histoplasmin 95 (20.3 per cent) reacted whereas of 469 given coccidioidin only 20 (4.3 per cent) reacted. Similar percentages were reported from this hospital in the preceding two years.

### DIAGNOSES

The diagnostic findings in general did not differ greatly from those reported at Fitzsimons Army Hospital in 1953. A diagnosis of tuberculosis in some form was established in 366 (76.1 per cent) of the military patients. The categories are listed in table 2.

TABLE 2 Categories of tuberculosis in 366 of 481 military patients

Category	Number	Per cent
	366	100.0
Total	4	1.1
Pulmonary tuberculosis	3	0.8
Arrested	117	31.9
Primary	134	36.6
Active minimal	54	14.7
Active moderately advanced	39	10.7
Active far advanced		
Tuberculous pleurisy	3	0.8
Tuberculosis extrapulmonary	2	0.6
Of mediastinal lymph nodes	1	0.3
Of superficial lymph nodes	1	0.3
Of kidney	4	1.1
Menigitis	3	0.8
Disseminated from lungs	1	0.3
Miliary		
Unclassified		

More of the cases of active pulmonary tuberculosis among personnel in the naval service were discovered by routine roentgenography (84 or 62.3 per cent) than by investigation of symptoms caused by tuberculosis (54 or 37.7 per cent). The situation was almost the reverse among a comparable number of Air Force personnel. Fifty-seven (40.1 per cent) of these were first de-

ected by roentgenography and 85 (59.9 per cent) because of symptoms. This difference probably arises from the practice in the Navy and Marine Corps of taking annual photofluorograms of personnel.

Twenty one of the military patients were first found to have pulmonary tuberculosis while under treatment for other diseases or injuries. Even this small number emphasizes the value of tuberculosis case finding programs in general hospital populations.

Of the 39 patients with tuberculous pleurisy, 33 presented themselves because of symptoms (nearly always pleuritic pain, fever, cough, and dyspnea of abrupt onset). Three, who claimed to be asymptomatic, were detected by routine roentgenography. In 3 cases, the disease appeared while the patients were under treatment for trauma, acute diarrhea, and anemiasis, respectively.

The nontuberculous entities encountered, most of which are self explanatory, are listed in table 3. These conditions posed the differential diagnostic problems. Percentages are not stated because the whole numbers approximate the percentages.

The most unusual differential diagnostic problem was that presented by a man with a nondescript, bilateral, pulmonary infiltration and dysphagia. Examination revealed cardiospasm with regurgitation of esophageal content into the tracheobronchial tree.

The instances of pleurisy classed as nontuberculous were those occurring in patients who failed to react to tuberculin.

The diagnosis of histoplasmosis is difficult to establish with certainty because it seldom can be proved mycologically. It usually is made either by excluding tuberculosis by means of the tuberculin test or by an evaluation of often incomplete evidence in the case of a patient who reacts to tuberculin as well as to histoplasmin. In all of our 18 cases, the possibility of tuberculosis was eliminated as certainly as possible, by bacteriologic cultures. In two cases, *Histoplasma capsulatum* was identified in "coin lesions" resected from patients, both of whom had been transferred from Panama. Thirteen of the remaining patients were "histoplasmin positive, tuberculin negative," but the other three reacted to both antigens. One of these three, also admitted from Panama, had a pneumonitis that cleared in a few weeks. He has remained well for a year. The other two men, from Tennessee and Kentucky, respectively, displayed pulmonary calcifications only.

Activity was deemed to be present in eight cases because of exudative pulmonary lesions, histoplasmosis complement fixation titer of 1:16 or greater, or report of a granuloma in a liver biopsy, singly or in combination

TABLE 3 *Nontuberculous diseases seen in 115 of 481 military patients*

Nontuberculous disease	Number
Total	115
Histoplasmosis	18
Medical observation	14
Infiltration pulmonary, cause undetermined	13
Calcification pulmonary cause undetermined	9
Granuloma pulmonary cause undetermined	9
Pleurisy chronic nontuberculous	7
Fibrosis pulmonary cause undetermined	7
Pleurisy acute serous cause undetermined	5
Pneumonia primary atypical	4
Bronchitis chronic	4
Sarcoidosis	3
Pneumonia not elsewhere classified	3
Abscess of lung	3
Carcinoma of lung	2
Empyema pleura	2
Bronchiectasis	2
Coccidioidomycosis	1
Bronchitis acute	1
Bronchopneumonia	1
Adhesions of pleura	1
Pneumothorax spontaneous	1
Pneumonia interstitial chronic	1
Atelectasis cause undetermined	1
Peritonitis chronic cause undetermined	1
Achalasia	1
Physical examination	1

Treatment of active cases of histoplasmosis consisted of rest with or without resection of lesions. All patients were ultimately returned to duty.

Throughout the year, an increasingly successful attempt was made to minimize the use of the diagnostic terms "infiltration," "calcification," and "fibrosis, pulmonary, cause undetermined." It is not uncommon for the physician to base his opinion and case-management on probabilities,<sup>6</sup> and careful evaluation of the evidence at hand will usually lead to more definite conclusions in cases so labeled. We retain the term "granuloma, pulmonary, cause undetermined," however, for the postsurgical case in which even the pathologist has been unable to make an etiologic diagnosis. When the ultimate in contemporary technique, namely, histologic and microbiologic examination of excised tissue, has failed, it appears logical to admit the failure and avoid stigmatizing the patient.<sup>7</sup>

### TREATMENT

With the exception of an older, emphysematous man whose "coin lesion" was removed for suspected carcinoma, all patients having active tuberculosis were treated initially with modified bed rest and chemotherapy. Chemotherapy was prescribed for 217 patients according to the Veterans Administration—Armed Forces Protocols for the Chemotherapy of Tuberculosis.<sup>8,9</sup> Such therapy could not be applied to 81 cases already committed to another program prior to arrival, nor to 37 cases because of the timelag between expiration of the 1955 protocols and receipt of their 1956 successors. Protocol therapy was not used in 28 other cases for miscellaneous reasons, including manifestations of tuberculosis not covered by protocols, patient intolerance of drugs prescribed, and administrative oversight.

Three severe hypersensitivity reactions were encountered: 2 to streptomycin and 1 to para-aminosalicylic acid.

Forty-two patients received some form of surgical therapy, other than thoracentesis. There were 34 unilateral subssegmental or segmental resections, 1 bilateral segmental resection, 1 lobectomy, and 1 pneumonectomy. There also were 1 spine fusion for tuberculosis of the vertebrae, 1 decortication, and 1 plastic repair of the chest wall after incision and drainage of a cold abscess. Many of the patients who were transferred to Veterans Administration hospitals were candidates for surgical treatment at a later date.

### DISPOSITION

Nontuberculous patients were either returned to duty or transferred to other departments of the hospital. The single death ascribed to tuberculosis was that of a man whose military meningial disease escaped attention for some weeks before he was admitted to the sick list. Interestingly enough, this man was

brought to medical attention by his friends because of a personality change simulating schizophrenia

The disposition of military patients with pulmonary tuberculosis is shown in table 4. There were no irregular discharges.

TABLE 4 Disposition of 308 military patients with pulmonary tuberculosis

Service	Recommended for duty	Transferred to V A hospitals	Other disposition
Total	42 (13.6%)	259 (84.1%)	7 (2.3%)
U S Navy and Marine Corps	10	139	1
U S Air Force	30	113	5
U S Army	2	7	1

Discharged administratively  
Transferred for humanitarian reasons to other military hospitals to complete treatment

Eight of the 39 patients with tuberculous pleurisy were returned to duty after treatment. 30 were transferred to Veterans Administration hospitals and 1 was transferred for humanitarian reasons to another military hospital to complete treatment. The disposition of patients with extrapulmonary tuberculosis was individualized.

Ten years ago a military tuberculosis service concerned itself primarily with the elimination of the unfit, and 10 years hence improved therapy may have eliminated such a service, but in the meantime it conducts a salvage operation designed to prevent unnecessary waste of restorable manpower. We have not hesitated to recommend return to duty of selected patients with pulmonary tuberculosis, prescribing such limitations as may be indicated in the individual case. The field of posttreatment restrictions in this new era of chemotherapeutically and surgically treated cases is in a state of chaos, often dominated more by opinion and dogma than by facts. In these circumstances, we base our planning on observation of former patients returned for periodic reevaluation, on the findings of Chamberlain and associates,<sup>10</sup> and on five year follow up results of surgical treatment at this hospital as yet unpublished.

Bearing in mind the crowded conditions of life aboard ship, we have been particularly conservative in recommending return to duty of naval and Marine Corps personnel after treatment for pulmonary tuberculosis. The 10 patients so recommended were

all stable individuals over 30 years of age who had received at least one year of effective chemotherapy. Eight of them had undergone successful resectional surgery, and all had been rehabilitated to full activity.

Of the 26 supernumerary patients, 25 proved to have tuberculosis. Treatment was either begun or continued until suitable disposition could be arranged. Three of the retired Navy men died, 2 of arteriosclerotic heart disease intercurrent in active tuberculosis and 1 of carcinoma of the lung and Friedländer bacillus empyema intercurrent in an old inactive tuberculosis.

#### SUMMARY

From October 1955 to September 1956, 507 patients were discharged from the tuberculosis service of this hospital.

Of the 507 patients, 481 (94.7 per cent) were members of the U. S. Armed Forces on active duty. Of these military patients, 366 (76.1 per cent), had some form of tuberculosis. The remaining 115 (25.9 per cent) had other diseases and presented problems in differential diagnosis.

Diagnostic findings, in general, did not differ greatly from those reported at Fitzsimons Army Hospital in 1953.

Active pulmonary tuberculosis was discovered by routine photofluorography in 84 (62.3 per cent) and by investigation of symptoms in 54 (37.7 per cent) of the patients from the Navy and Marine Corps. Among a comparable number of Air Force personnel, 57 (40.1 per cent) patients with active pulmonary tuberculosis were first discovered by roentgenography and 65 (50.1 per cent) by investigation of symptoms.

Twenty-one military patients were discovered to have pulmonary tuberculosis while they were undergoing treatment for other diseases or injuries. This emphasizes the value of tuberculosis case finding programs in general hospitals.

Non-tuberculous conditions that often were difficult to distinguish from tuberculosis were histoplasmosis, and pulmonary infiltration, calcification, or granuloma, of unknown, but non-tuberculous cause.

Ten Navy and Marine Corps patients were recommended for duty after treatment for pulmonary tuberculosis.

---

Death is something that even doctors shy away from discussing with patients facing it. To allow and even draw them out about it is most demanding and stirs up considerable anxiety within the therapist. In fact there is a great temptation to escape a discussion of death by diverting the patient from this topic or offering meaningless platitudes. Much fear can be banished and much courage and tranquility can be achieved if the doctor can be a little less afraid than the patient."

# INCREASING DENTAL SPEEDS

FRANK J BRAUER *Commander DC USA*

**G.** V BLACK<sup>1</sup> once stated that, "The professional man has no right to be other than a continuous student," and rapid advances in dental operative instruments during the past few years have made this statement especially applicable to our present period. The range of speed available to the profession has increased to such an extent that we have far surpassed what Walsh and Symmons<sup>2</sup> advocated in 1949, however, there still is little agreement as to what is the optimum speed of rotation. The answer will have to be derived by the slow process of correlating clinical and laboratory data. We cannot make snap decisions in either laboratory or clinic, but must patiently weigh and evaluate our results, and from the mass of accumulated information evolve what is best for the profession.

Over past decades, the various specialties of dentistry advanced to a remarkable degree, but not until 1940 to 1946, in conjunction with advances being made in precision instruments, machine tool manufacture, and diamond and carbide burs, did operative dentistry begin to come into its own. Whereas in the past we all have experienced difficulty in penetrating the occlusal enamel, penetration now can be accomplished in a matter of seconds. New concepts in operative techniques<sup>3</sup> have shortened operative time to such a marked degree that chair time may be reduced by 50 to 60 per cent, depending on the type of restoration.<sup>4, 5</sup>

## METHODS OF INCREASING SPEEDS

The types of power being used or investigated at present are (1) air, (2) water, and (3) motor. Although none of these are new in concept, the various applications are interesting and time alone will tell their relative value.

**Air Turbine Handpiece.** Air has been studied as a possible power source by several investigators in various parts of the world. Tanner and Mitchell<sup>6</sup> reported that speeds of 55,000 r p m and higher were attained with an instrument running free. A small

---

From U S Naval Dental School, National Naval Medical Center, Bethesda Md.  
Comdr Brauer is now at Naval Station, Navy No 127 c/o Postmaster, Seattle Wash.

turbine is located in the head of the handpiece resulting in a compact balanced instrument

Stephens described two experimental models with speeds in the 25 000 to 35 000 r p m range Large turbines are located on the spindle end of these instruments, and rotor speed of 50 000 to 70 000 r p m were obtained When used with the Imperator handpiece speeds were about 35 000 r p m Acrylic was used in the housing and rotor in an effort to study the functioning of these experimental models

The air driven handpiece described by Peyton<sup>1</sup> has a speed of about 75 000 r p m when cutting and higher speeds when running free The turbine is located on the spindle end of this handpiece

At the present time there is an indication that several handpieces utilizing the air turbine principle will soon be available commercially and will attain speeds in the 200 000 to 300 000 r p m range

**Water Turbine Handpiece** There are several experimental models of water turbine handpieces and one type is now commercially available A water turbine (hydraulic) handpiece developed at the University of Michigan operates at about 60 000 r p m The rotor or drive turbine of this instrument is located on the spindle end

The hydraulic handpiece developed by Nelson Pelander and Kumpula is in the 61 000 r p m range It has a small drive turbine in the head of the contra angle

Both air turbine and water turbine instruments are free of the usual engine arm and belt sources of vibration Because of a minimum number of moving parts they also are relatively free of heating These instruments have low torque values and can be stopped readily by heavy loads or pressures applied to the cutting tool so that stones large sized diamonds and disks are relatively ineffective The air turbine handpiece offers slightly higher torque values making it effective with burs This may be due to the slightly greater mass of its impeller or turbine The low torque relation of many of these new instruments actually is of value for those who have a tendency to bear down or use too much pressure in cutting procedures

A hard water source may create a slight problem with the water turbine instrument A major problem with the air turbine handpiece in the past has been the high noise level created by the escaping air but newer models have insulation in and around the turbine head to eliminate some of the noise

**Motor Driven Handpiece** A dental handpiece with a small electric motor attached to the spindle end of the instrument was developed at the University of Michigan for the United States Army.<sup>4</sup> The latest model was built by the Hannu Engineering Company, Inc. This instrument operates from a 12-volt-battery source and develops 15,000 r p m with a straight handpiece and 9,500 r p m with contra angle. The contra angle attaches to the straight handpiece by a sleeve union. It would be interesting to see what the increase in r p m would be with one of the newer contra angles that increase the r p m 2½ times in the contra angle head. The average handpiece weighs 5½ to 6 ounces. This instrument weighs 6½ ounces and is well balanced. The stalling torque is 2.8 ounces.

This instrument offers many possible uses in the sick room, hospital, remote areas, et cetera. The Army Research and Development Division is now field testing it for military applications. Indications are that a handpiece of this type will be made available commercially in the near future. It will contain a belt ratio drive from the motor to the contra angle head and will develop speeds well into the 100,000 + r p m range.

**Motor of Unit** In a survey of 50 units being used by practitioners, Kilpatrick<sup>10</sup> found a maximum range of 6,000 r p m, with an average of about 3,500 r p m. Most manufacturers now provide a multiple speed unit with a more powerful engine and a selection of speed ranges. In the old type unit having normal speeds of 4,000 to 6,000 r p m, opening the shunt resistance of the motor circuit will produce approximately the following speeds for units of the makes indicated: (1) S. S. White Dental Manufacturing Co., 8,500 to 9,000 r p m, (2) Ritter Co., 10,000 to 13,000 r p m, (3) Weber Dental Manufacturing Co., 16,000 r p m.

According to the manufacturers, motors will tolerate the increased speeds without excessive wear, provided they have plastic insulation between the poles of the commutator instead of the old type mica insulation. The resistors are porcelain tubes about 4 inches long, light green or white in color, lying in a horizontal or vertical position within the dental unit. A toggle switch placed in the wiring circuit will give increased speeds when the resistors are cut out. This change does not affect the automatic breaking of the series wound motor.

**Engine Pulley** An increase in the diameter of the engine pulley by a ratio of 2:1 over the diameter of the handpiece pulley will increase the operating speed by about the same amount.<sup>7</sup> The average present-day engine pulley is 1 to 1½ inches in diameter. By increasing the size of the pulley to 2½ or 3½ inches, speeds up to 20,000 r p m can be attained.

Delta and the tension plays an important part in  
increased slack, which also adds a safety  
factor as much as 2,000 r p m. By  
lengthening the rotating handpiece, proper adjust-  
ment of the belt can be made. Kilpatrick<sup>11</sup> suggested the  
use of a belt to lessen slippage tendencies.

Various bolts have been investigated and tested in an attempt  
to prolong the life of most bolts may be lengthened  
by washing the bolts once or twice a month and allowing  
the belt to dry out before using.

Friction is the main foe to increasing handpiece  
speed. In the idler pulleys on the belt armature and  
replacing the ball bearing idler pulleys friction will be  
reduced to a range of 6,000 to 10,000 r p m can be ob-  
tained. This helps to eliminate some of the drag on the  
dentist.

**Handpiece Improvements for Higher Speeds.** Manufacturers have ap-  
proached the problem of improving handpieces for use with higher  
speeds in different ways. Some of their improvements are: modi-  
fied sleeve bearing metal bearing surfaces that are self-aligning  
on the shaft; use of ball and socket principle; stainless steel ball  
bearings; improved chucks; improved bur insert and latch (made of  
hardened steel or carbide); closer tolerances; longer shafts;  
phosphor bronze sapphire needle or glass bearings; rat belt  
drive (no gears); automatic oil mist (no oiling); self-contained  
water spray; and self-contained air cooling.

This is not a complete list but it indicates the types of im-  
provements that have been made in handpieces to go with higher  
speeds.

## VIBRATION STUDIES

Vibration is a nuisance factor that causes tension and apprehension in the patient. In 1948 and 1949 Walsh and Symmons<sup>12</sup> published their far-reaching reports on vibration perception. Their basic work was a milestone for the dental profession. All their tests were performed with an oscillometer on the upper central incisors of patients. They found that the upper threshold of sensation was from 500 to 600 cycles per second (c p s) with a mean of 560 c p s. Maximum unpleasantness occurred from 100 to 200 c p s with a mean of 178.2 c p s. The range of vibration caused by the dental handpiece was found to be from 95 to 115 c p s with a mean of 111 c p s which falls within the maximum unpleasantness range. As a result of their studies Walsh and Symmons also concluded that the harder the material being cut the higher the harmonics.

Henry and Peyton,<sup>14</sup> in their vibration studies of rotating dental instruments, came to the conclusion that when operating with light pressures there is a tendency for the amplitude of vibration to decrease as the speed is increased, with the larger burs showing a greater vibration characteristic.

Sources of possible unpleasant vibrations include poor adjustment (contra angle and handpiece), worn clutch, latch, bur seat (internal play), or bearings, frayed belt belt vibration, and eccentric bur vibration. In short, any movable part of the system can contribute to vibration. To overcome some of the handpiece vibration, several manufacturers have changed to longer shafts, and instead of gear drive have used a belt drive or the turbine principle.

Hudson and associates<sup>15</sup> showed by high speed photography that an eccentric rotating dental instrument in an increased speed range of 6,000 to 10,000 r.p.m. can cause vibration of 100 to 200 c.p.s., which is in the unpleasant range for the patient, and that true running burs produce a ratio well above 600 c.p.s. when rotated at the same speeds.

#### TEMPERATURE STUDIES

Hensel and Mann<sup>16</sup> showed normal body temperature caused of patients. This seems to which he showed the pain tolerance zone patients to be from 85° to 130°F.

**Bur Temperature** In studies of dental cutting instrument the temperature of the head of thermocouple wire was soldered and connected to a Brown which recorded the temperature of dentin with the tooth held in normal cavity preparation, at 2,000 r.p.m. and of 27 temperatures as high as 35° penetrated the occlusal enamel with a No. 8 round bur and temperature of or over 600°F.

In changing to a bakelite properties to dentin, the following temperature developed in a force of 200 grams (about was approximately 150°F slope of the bur blade under

at a variance of 10°C from the pain at the dentoenamel junction or with Hensel's studies,<sup>17</sup> in which zone patients to be from

temperature developed in rotating burs were measured by using a constantan thermocouple of a test bur connected to a potentiometer, data recorded on bur. In cutting the bur under pressure as in denture were recorded of 150°F at 2,000 r.p.m. In some cases, when cutting in attempting to cut a tooth at 500 r.p.m. of a round tooth - 7500 r.p.m. of a tungsten carbide bur, a record was

also obtained in practical work. Results were obtained (1) The difference between the bur blades with the same speed of a round bur, (2) The temperature of the cutting

(3) The temperature of the bur blade and base to be constant

to be highest for the slope of the curve tends to 24 000 r p m

### Tooth Temperature

used speeds of 30 000 r p m with 1/2 to 1 lb maximum temperature conclusions after 10 seconds after

temperature rise was less than steel bur. Carbide bur produced less rise in temperature than steel bur that turned faster produced less

in 1951 to 1955, Poyton and Vaughn<sup>11-12</sup> used speeds up to 11 000 r p m. The maximum temperature is reached in 10 seconds after 10 r size burs produced a lower temperature rise than steel burs. Carbide burs produced less rise in temperature than steel burs with the findings of Lammie<sup>13</sup> that carbide burs cut faster, lasted longer and produced less mass of enamel cut than steel burs.

In 1951, Poyton and Vaughn<sup>11</sup> tested inverted cone type bur. The diamond point bur used the inverted cone point. Using No 37 burs with 1 lb pressure and with no coolant the steel bur produced a temperature rise of 70°F at 10 000 r p m which was 20°F at 1 lb pressure and 25 000 r p m, the carbide bur 50°F at 1 lb pressure and 10 000 r p m and 170°F at 1 lb pressure and 25 000 r p m and the diamond point, 40°F at 1 lb pressure and 10 000 r p m and 150°F at 1 lb pressure and 10 000 r p m.

A temperature rise of about 15°F was noted with the water spray coolant. When 1 lb pressure was used the water was effective in keeping the temperature rise in the tooth to less than 20°F. With no coolant, the No 37 carbide bur showed a temperature rise of slightly less than the steel bur and the rise was almost the same for carbide as for steel burs when using coolants. The diamond instruments showed less temperature rise than was shown by the burs under all comparable conditions of study. The carbide bur generally caused a little less temperature rise in the tooth than the steel bur. It is interesting to note that these studies measured temperatures generated in the tooth structure and not in the cutting instrument as in Hudson's studies.

To measure the temperature of the structure being cut Vaughn and Peyton<sup>1</sup> inserted a small thermocouple into the tooth at the dentoenamel junction then cut away the tooth tissue until the thermocouple was exposed.

Isanti and Zander<sup>14</sup> stated that the tooth is capable of dissipating heat rather efficiently less elevation being noted in

the thicker layers of dentin, but concluded that physiologic changes occur in the dental pulp at temperatures above 130°F

**Coolants** A coolant is needed for any increase in handpiece speeds, and water spray is the most effective under practical conditions, with only a 15°F rise in temperature noted at 30,000 r p m. A water stream could keep this temperature rise to 1° to 2°, but this would require 50 ml/min. The saliva ejector is not adequate for handling this amount of liquid and thus additional equipment would be required. At a flow of 18 ml/min, there is a 40°F rise of temperature. Air is not as effective, especially on diamonds, and the temperature rapidly rises with increasing r p m. Disks in general are not as easily cooled as burs, but perforated disks are more easily cooled than solid ones.

According to Doerr,<sup>14</sup> the advantages of using a coolant are that it eliminates heat and protects the pulp, tends to keep the cavity clean, prevents clogging of instruments, acts as a lubricant, cushions vibration to a certain extent, increases life of burs and diamonds, and makes it easy to remove old restorations. He lists as disadvantages the need for hose attachments, interference with vision, and splattering of mirror (a detergent used on the mirror will help to lessen this effect).

#### EFFICIENCY OF CUTTING INSTRUMENTS

From the tests conducted on the efficiency of cutting instruments, Hudson and Associates<sup>15</sup> concluded that when cutting dentin, steel and carbide burs have equal cutting rates at either 5,000 or 10,000 r p m. When cutting enamel at 5,000 r p m, steel and carbide bur cutting rates are substantially the same (the life of the steel bur is much shorter), but at 10,000 r p m carbides cut twice as fast as steel. At either 5,000 or 10,000 r p m, diamonds are more effective than either type bur.

Poyton<sup>16</sup> conducted tests with speeds up to 18,000 r p m on Iverine and concluded that (1) the rate of increase in efficiency is maintained rather consistently for the higher operating speeds, (2) it is not to be expected that all burs will show an equally effective increase in efficiency with an increase in operating speed, (3) the spiral type bur is more effective than the straight fissure bur at all operating speeds up to 18,000 r p m, because the straight fissure bur had more of a tendency to become clogged, (4) the amount of material removed is dependent upon the pressure applied, and (5) the No. 37 inverted cone bur showed one third as much active area as the No. 557 straight groove fissure bur, but will remove five times the amount of material per unit time as the fissure bur. On the basis of unit active area, a ratio of approximately 15:1 exists in favor of the inverted cone bur.

**Higher Speeds of Rotation** Ingraham and Adelson<sup>25</sup> using ivory in their studies of cutting efficiency of the No 558 carbide bur and speeds up to 40 000 r p m, concluded that cutting efficiency increased with increase in speed and that doubling the pressure applied approximately doubled the rate of removal. More laboratory studies are needed at the higher speeds of rotation up to and including the 200 000 r p m range. Out indications are that steel burs are ineffective carbide burs maintain their efficiency at the higher ranges of speed carborundum stones increase in efficiency at the higher ranges and diamond instruments maintain their efficiency although this seems to be dependent upon peripheral speed.

The term r p m means little at present and the more important consideration is the rim (peripheral) speed of the instruments. According to engineering and machine principles, diamonds are supposed to be more or most effective in the 5,000 to 9 000 feet per minute range.<sup>26</sup> The 1/8 inch diameter diamond instrument at 30 000 r p m has an approximate rim speed of 1 000 feet per minute. To achieve a rim speed of 5 000 feet per minute, the r p m would have to be about 150 000. The 1 inch diameter diamond instrument rotating at 20,000 r p m will achieve peripherally some 5 000 feet per minute.

**Design and Shape of Burs and Diamond Instruments** The best shape for cutting burs is not definitely known and many different investigators as well as the manufacturers have been working on this problem for a long time.

**Manufacture of steel burs** The bur itself is dependent upon the steel used.<sup>27</sup> Automatic screw machines are used for blanking then burs are milled or head cut to produce the flutes or teeth. Some machines cut the side and end flutes in one continuous operation while other machines only perform one operation, thereby necessitating a second cutting step. After processing the burs are hardened by a salt bath and polished.

**Carbide burs** Tungsten carbide burs are manufactured<sup>28</sup> by first making the steel shaft and brazing soldering or welding the tungsten carbide to this shaft. The bur head or flutes are cut with diamond instruments. A sintered head carbide bur is available in which the tungsten is held together by almost pure cobalt. These burs can withstand temperatures up to 800 F. The steel shafts are prone to rust if left in a strong oxidizing agent or in various types of chemical sterilizing agents. Carbides are more efficient at high speeds.<sup>29</sup> Reversing direction or side pressure may fracture blades. The bur should be rotating before being brought into contact with surface being cut and better

control is assured by moving the bur in a clockwise direction around the cavity walls.

Henry<sup>10</sup> has reported on the problem of bur design in relation to true cutting and to clogging tendencies as affected by end flutes and changes in bur diameter, cutting length, and number of flutes. As the number of blades is decreased, the magnitude of forces at each blade increases and the thickness of chip removed by each flute should increase correspondingly. A smaller number of flutes increases the space between flutes and decreases the clogging tendency. In removing more material, each flute shows more tendency for flute wear and cutting life is decreased. Small or number of flute are more vibratory. Henry concluded that (1) only the last one thousandth of an inch of flute edge is effective for cutting soft material, and this distance decreases as the hardness of the material increases until in some cases only a few micro inches of blade edge are effective, (2) the finish does not have much effect, and (3) heat treatment has a slight effect but burs without it cut equally well.

In a previous study of changes in the rake angle, Henry and Peyton<sup>11</sup> concluded that (1) a more negative rake angle cuts less but resists dulling more, and (2) the cutting efficiency of the bur is correlated with the angle and the percentage clearance space (at speeds up to 12,000 r p m using Ivorine).

The bur manufacturers have production and labor costs to contend with in trying to produce a relatively inexpensive bur, and the small increase in efficiency does not necessarily warrant the added cost. Undoubtedly with the increase of speeds of rotation, design and efficiency experimentation might result in closer tolerances and standardization of the dental bur in the future.

*Diamond instruments* The small diamonds are retained on the base by electroplating them into the metal matrix (electrolytic amalgamation). The diamond is held in place by mechanical retention. Peripheral speeds from 5,000 to 9,000 foot per minute are required for efficient operation.<sup>12</sup> Using the largest wheel possible to perform the cut will extend the life of the instrument. Diamond functions best on hard structures. Light pressures should be used. Better control of the instrument is had by using a dragging motion and not attempting to push it into the structure being cut. Coolant water spray helps minimize clogging and heat production. A clogged diamond is an inefficient and ineffective cutting instrument.

To clean diamond instruments, several methods may be used. Liquid and cream type cleaners containing oxygenating chemicals should be used with a stiff brush. Rubber abrasive, or ink eraser

should be used at high speed and light pressure. Hard stick abrasive resembles light baked ceramic and should be soaked in water or run under water when being used. To remove amalgam, heat the instrument lightly over a gas flame or soak in mercury overnight.

### CONCLUSIONS

The use of increased dental speed has both advantages and disadvantages. Some of the advantages are that less pressure is required and less fatigue is produced; the operator has more control; the patient feels less vibration; the efficiency of burs and diamonds is increased, and chair time is decreased.

Disadvantages consist of the special practice and trained tactile sense required at high speed; the necessity of using coolants which tend to obscure the field of operation; the need for more exacting care and maintenance of equipment; or for purchasing new and expensive equipment; the unpleasant noise level; the greater wear on ball bearings, clutch and bur seat; the greater possibility of pulp damage; and the necessity for efficient aspiration.

### SUMMARY

Dental handpiece speeds have increased rapidly in the past 10 years and speeds in the 200 000 to 300 000 r.p.m. range are not uncommon. Innovations introduced to produce high speeds include the water turbine, the air turbine, and increased ratios of gears, belts, and pulleys. Friction is the main obstacle and various manufacturers have introduced improvements in handpieces to overcome it.

The vibration produced by rotating dental instruments has long been annoying and distressing to the patient. The frequency of vibration produced at low speeds is in the most unpleasant range, while true running burs and diamonds operated at high speeds produce vibration well above the unpleasant frequency range. Many factors play a part in producing unpleasant vibration and manufacturers of dental instruments and handpieces have used various approaches to meet this problem.

Increased temperatures are produced by increase in either handpiece pressure or rotational speed. To dissipate the heat produced by increased speed, a coolant must be employed, water spray being the most effective.

The efficiency of carbide burs and diamond instruments increases with increase in speed, specifically rim (peripheral) speed.

Increased speed offers certain advantages, but involves some disadvantages. Extensive laboratory and clinical studies will be required to determine optimum speeds of rotation, effective efficiency ranges of carbide burs and diamond instruments, and many other problems associated with high speeds.

# REDUNDANCY OF THE SIGMOID COLON

PETER ZANCA *Colonel MC USA*

**B**ORDERLINE anatomic variations and anomalies of the esophagus and gastrointestinal tract that cause few symptoms attract little attention and seldom are the subject of an interesting scientific report. Redundancy of the colon is one of these borderline conditions which is only casually mentioned and usually is not given serious consideration either in differential diagnosis or for the symptoms it produces. The tendency to disregard this anatomic variant is common. Actually, redundancy of the colon occurs in from 15 to 25 per cent of the general population and in about 60 per cent of all patients who suffer with chronic constipation. It should be strongly considered and differentiated from aganglionic congenital megacolon.

The purpose of this article is to emphasize the high rate of occurrence of redundancy of the colon in infants and children, and especially of the sigmoid flexure of the colon, and to re-emphasize the point that this condition should be seriously entertained and ruled out before a working diagnosis of congenital aganglionic megacolon is made. Definite diagnosis of Hirschsprung's disease is made only after surgery and on histologic study of the bowel specimen.

Since Swenson, Neuhauser, and Pickett<sup>1</sup> brought our attention to the anatomic abnormality responsible for congenital megacolon, we have become aware of all of the signs and symptoms that lead to this diagnosis. The emphasis on this condition is so great that both pediatricians and radiologists sometimes are inclined to establish the diagnosis of Hirschsprung's disease on minimal or doubtful radiological findings. The difficulty mainly involves proper interpretation of the rectosigmoid area and areas of dilatation of the colon.

Roentgenographically, the diagnosis of Hirschsprung's disease is made when there is a constant narrowing of the rectosigmoid area for a variable distance, with dilatation of the colon proximal to the constricted area. In most cases, there is some loss in the haustral markings of the colon and some decrease in the peristaltic activity of the dilated portion of the large bowel.

# REDUNDANCY OF THE SIGMOID COLON

PETER ZANCA *Colonel MC USA*

**B**ORDERLINE anatomic variations and anomalies of the esophagus and gastrointestinal tract that cause few symptoms attract little attention and seldom are the subject of an interesting scientific report. Redundancy of the colon is one of those borderline conditions which is only casually mentioned and usually is not given serious consideration either in differential diagnosis or for the symptoms it produces. The tendency to disregard this anatomic variant is common. Actually, redundancy of the colon occurs in from 15 to 25 per cent of the general population and in about 60 per cent of all patients who suffer with chronic constipation. It should be strongly considered and differentiated from aganglionic congenital megacolon.

The purpose of this article is to emphasize the high rate of occurrence of redundancy of the colon in infants and children, and especially of the sigmoid flexure of the colon, and to re-emphasize the point that this condition should be seriously entertained and ruled out before a working diagnosis of congenital aganglionic megacolon is made. Definite diagnosis of Hirschsprung's disease is made only after surgery and on histologic study of the bowel specimen.

Since Swenson, Neuhauser, and Pickett<sup>1</sup> brought our attention to the anatomic abnormality responsible for congenital megacolon, we have become aware of all of the signs and symptoms that lead to this diagnosis. The emphasis on this condition is so great that both pediatricians and radiologists sometimes are inclined to establish the diagnosis of Hirschsprung's disease on minimal or doubtful radiological findings. The difficulty mainly involves proper interpretation of the rectosigmoid area and areas of dilatation of the colon.

Roentgenographically, the diagnosis of Hirschsprung's disease is made when there is a constant narrowing of the rectosigmoid area for a variable distance, with dilatation of the colon proximal to the constricted area. In most cases, there is some loss in the haustral markings of the colon and some decrease in the peristaltic activity of the dilated portion of the large bowel. There also

From U S Army Hospital, Fort Dix, N J.

is a loss in the normal peristaltic activity of the narrowed segment of the colon in the rectosigmoid area and the rectum itself appears normal in caliber and in function. The roentgen manifestations of Hirschsprung's disease have been well demonstrated in the literature. I should like only to re-emphasize the need for oblique and lateral views of the rectosigmoid area because the narrowed segment of the colon is best seen in this way.

With a patient having a history of chronic constipation, abdominal distention, difficulty in defecation and passage of small hard stools, the physician will order a barium enema examination with the aim of establishing or ruling out intrinsic organic disease or functional disease of the large bowel. When these symptoms are present in children and in infants, the possibility of congenital megacolon is immediately entertained. Under such circumstances the barium enema examination is done and the roentgenographic findings frequently are equivocal.

Redundancy of the colon is a condition in which the colon is unduly long or dilated. It may form extra bowel loops and may lie in various positions within the abdominal cavity. Kantor<sup>2</sup> described three common varieties of redundant colon: (1) the centrally placed sigmoidal loop that rises out of the pelvis, (2) "double splenic flexure with straight efferent loop" and (3) "pelvic loop to the right." Redundancy of the sigmoid colon, as used in this article, refers to the long intrapelvic portion of the large intestine which rises high above the pelvic brim in the abdomen to a level above the intercrural line of the bony pelvis. This segment of the colon may lie in the midline or extend to the right or left abdominal regions.

The diagnosis of redundancy of the colon is easily made when a large part of the colon is involved; however, the problem of diagnosis remains when we are dealing only with redundancy of the sigmoid colon. Accurate diagnosis of this condition in children is especially important when the possibility of congenital aganglionic megacolon is considered.

In the usual normal colon the sigmoid flexure of the large bowel lies well within the pelvis on the roentgenogram of the barium-filled colon (fig. 1). The diagnosis of redundancy of the sigmoid colon can be made from the roentgenogram when the superior margin of the sigmoidal loop extends well above the intercrural line of the bony pelvis after the colon is distended by either air or fluid (barium) as shown in figure 2. In this type of colon the rectosigmoid area appears normal and there is normal peristalsis throughout the large bowel. With the large bowel emptied the sigmoid flexure of the colon is seen to descend into the pelvis (fig. 3).

*Figure 1 Normal colon distended with barium. Note position of various segments of the large bowel in relation to the bony pelvis.*

The roentgenographic finding of the sigmoidal loop above the level of the pelvic inlet, with absence of a narrowed segment of the colon and with normal peristaltic function, is sufficient to differentiate this condition from congenital megacolon. The final diagnosis of redundancy of the sigmoid colon is made, however, after the following conditions are ruled out: (1) organic disease distal to rectosigmoid area, (2) functional disease distal to the rectosigmoid junction, (3) intrapelvic pathology, (4) mechanical disorders that are the result of some previous surgical procedure, (5) excessive weight loss, and (6) atonic colon following administration of drugs.

There are numerous variations of the colon which are found in individuals of different habitus. These may be due to con-

Figure 2 Redundancy of the sigmoid colon. Note high position of sigmoid flexure above intercrystal line of pelvis.

genital malformation of the bowel or secondary to malformation of adjacent tissues. In the colon, anomalies in length, malrotation or incomplete rotation of the gut, and anomalies of fixation of the bowel account for most of the variations. The sigmoidal redundancy may result from a congenitally malformed long or large segment of the bowel, functionally disturbed segments or hypermobility of the sigmoidal loop because of a large mesentery. Normally the sigmoid colon is held in place by the pelvic mesocolon. This mesentery may be large or redundant and so allow for mobility of the sigmoidal loop of the colon. In the average sized individual, the sigmoid flexure of the bowel will move only a limited distance when filled with fluid or gas. Usually it will not extend above the intercrystal line of the bony pelvis. Fixation of this segment of the bowel should arouse suspicion of intra abdominal or intrapelvic disease.

Figure 3 Postevacuation roentgenogram demonstrating empty colon with descent of sigmoid colon into its normal intrapelvic position.

Redundancy of the colon is a frequent cause of chronic constipation and should be ruled out in all patients having this symptom. Many textbooks mention that colonic redundancies constitute variations of normal and that they usually are of no pathologic significance. In some books, emphasis is made of the possible occurrence of fecal stasis in redundant segments of the large bowel, others emphasize the frequency of occurrence of volvulus and obstruction as a result of redundancy.

In 1934, Kantor<sup>3</sup> recorded an 18.5 per cent incidence of dolichocolon in 1,850 patients. In his series of patients, 66 per cent had had constipation from birth, 21 per cent complained of abdominal distention, and 55 per cent had abdominal pain. In reviewing 100 consecutive office case records of patients with some type of colonic dysfunction, Bockus and Willard<sup>4</sup> found

redundancy of the colon in 29 per cent. In 1949 Zeisel<sup>5</sup> reported four infants and children with chronic constipation and with redundancy of the sigmoid colon. Feldman<sup>6</sup> reported that the sigmoid colon is involved in over 50 per cent of all of the cases of dolichocolon. Portis<sup>7</sup> stated that the sigmoid colon lies in the pelvis in 90 per cent of adults, in 10 per cent it rises upward toward the umbilicus, a position usual in infants. This information was obtained from studies on cadavers. In roentgenographic studies of the living adult colon, Portis found the sigmoid colon above the pelvic brim in more than 10 per cent of the cases.

In 1956 we performed 200 barium enema examinations, many to rule out organic disease. Our patients included 14 infants and children and 186 adults, with an age range of from 3 weeks to 72 years. Some patients gave a history of chronic constipation, abdominal pain, and gaseous distention. Most of our patients had a variety of symptoms that included diarrhea, rectal bleeding, intestinal obstruction, ulcer, hemorrhoids, and possible intra-abdominal masses. Only 16 (9 per cent) of the entire group gave a history of chronic constipation. 182 (91 per cent) had other abdominal complaints and symptoms. Of the 16 patients with chronic constipation there were 12 (66.6 per cent) who had a redundancy of the sigmoid colon, in the other 4 the sigmoid colon was within normal limits. Of 182 patients having symptoms other than chronic constipation, there were 19 (10.4 per cent) with sigmoid redundancy. The over-all rate of occurrence of redundancy of the sigmoid flexure of the colon was 15.5 per cent (31 cases). Of special interest was the finding that 14 of the 31 cases (45 per cent) were infants or children. All of the infants and children in this random sample had redundancy of the sigmoidal flexure of the colon, of this group, 7 (50 per cent) had been studied mainly because of chronic constipation. Of the 186 adults 17 (9.1 per cent) had redundancy. We had 1 surgically and histologically proven case of aganglionic megacolon.

Kantor<sup>8</sup> emphasized the possible clinical syndrome of constipation, gaseous distention, and abdominal pain in patients with dolichocolon. We believe that more emphasis should be placed on this entity and that an attempt should be made to separate those cases from the true aganglionic megacolon, which is amenable to surgery. Faced with an infant or child with a history of chronic constipation, a barium enema examination should be performed and the following causes of constipation should be considered: (1) organic lesions of the bowel or adjacent tissues that cause mechanical obstruction; (2) functional conditions (those caused by improper diet, drugs, psychogenic disorders, poor bowel habits and sedentary life, and hypotonic or hypertonic intestinal tract); (3) diseases of peripheral nervous system; (4)

allergies, (5) trauma, (6) infection, (7) endocrinologic disorders, and (8) redundancy of the colon

The diagnosis of redundancy of the sigmoid colon can be made in the adult after study and evaluation of the history, physical findings, and roentgenographic picture. In the infant and child, diagnosis of this condition is sometimes difficult because the colon has not assumed its full grown, final, and fixed anatomic position in the abdomen.

In infants, multiple variations in position and caliber of the colon are common, as part of normal development and growth. The reader is referred to the excellent tracings in Caffey's *Pediatric X Ray Diagnosis* that demonstrate variations of the position of the colon in infants. These variations of development should be considered when studying the colon of infants and children, and in the absence of positive symptoms or history they should be considered as normal variants. With symptoms of chronic constipation, obstruction, distention, and pain, and in the presence of normally formed bulky stools, the possible diagnosis of redundancy of the colon should be entertained.

Management of the redundant colon is directed toward establishing good health habits with proper diet, avoiding drastic laxatives and enemas, and establishing regular time schedules for eating and defecation. Recently, beneficial effects and good results have been obtained by treatment with senna (*Cassia acutifolia*). Some cases of redundancy of the sigmoid colon have been successfully treated by segmental resection.

#### CONCLUSIONS AND SUMMARY

Redundancy of the colon is an anatomic, physiologic variant that is found in the newborn infant but persists into adult life in only a small per cent of individuals. Redundancy of the sigmoid flexure is the most common form, and is sometimes mistaken for aganglionic congenital megacolon.

From a study of 200 barium enema roentgenograms chosen at random, it may be concluded that the over all rate of occurrence of redundancy of the sigmoid colon is about 15 per cent. It is frequently found in children and infants, and is present in about 1 out of 10 adults. The incidence in adults who give a history of chronic constipation or have some other abdominal complaint is relatively low (9.1 per cent, or 17 of 186 cases in this series). The incidence of redundancy in infants and children who give a history of chronic constipation or of some other abdominal complaint is high (100 per cent, or 14 of 14 patients in our series).

The low rate of redundancy in the adult and the very high rate of redundancy of the sigmoidal flexure in children and infants

suggests that the redundant infantile colon might in some cases, revert to the normal anatomic and physiologic colon of the adult

Patients with redundancy of the colon are inclined to develop constipation and chronic constipation frequently is accompanied by or causes sigmoidal redundancy (in 12 of 16 cases 66.6 per cent in this series)

Accuracy of diagnosis of redundancy of the colon is essential in symptomatic patients for proper medical management

# THE SIGMOID SEGMENT AS A BLADDER SUBSTITUTE

JOHN W. SIMPSON *Colonel MC USA*  
WARNER F. BOWERS *Colonel MC USA*  
CLAUDE C. DODSON *Colonel MC USA*

**E** VISCERATION of the pelvic organs, whether it be for tumors of the internal genitalia, bladder, or colon, may require excision of the bladder, making it necessary to provide some method of dealing with urinary drainage. Essentially, there are three possibilities: (1) cutaneous ureterostomy, (2) wet colostomy, or (3) bowel segment substitute.<sup>1</sup> In each method there are definite hazards and complications, as well as favorable points for consideration. Probably there is a place for each of these procedures.

## CUTANEOUS URETEROSTOMY

Formerly, when more definitive procedures carried a prohibitively high mortality rate, bilateral cutaneous ureterostomy was an acceptable procedure. Now, however, it rarely is necessary to resort to this less satisfactory operation. Two urinary cutaneous fistulas plus a colostomy seem to be more than the patient should be asked to bear. Furthermore, the stomata are difficult to keep dry and repeated catheterization usually leads to infection. Cutaneous ureterostomy is indicated in severely ill patients who will not tolerate more extensive surgery, in cases where there is marked hydronephrosis and hydro ureter from tumor compression, and where there is marked reduction in kidney function either from pressure of obstruction or from urinary tract infection. In these instances cutaneous ureterostomy may be lifesaving, and a more acceptable procedure may be substituted later if the tumor is controlled and if kidney function improves sufficiently.

## WET COLOSTOMY

If kidney function is good and hydro ureter and infection are not prominent, implantation of the ureters into the intestinal tract is advisable. The simplest of these procedures is uretero-

sigmoid implantation, forming a wet colostomy. Cited as a disadvantage is the psychic trauma from absence of micturition, but surely this is not serious. The serious complications are (1) ascending infection which often is fatal, (2) ureteral obstruction at the site of anastomosis, (3) decreased kidney function incident to one of the preceding, (4) fistula formation, and (5) a large surface for reabsorption of urine. Inasmuch as it is relatively simple to form a separate loop into which the ureters can be implanted, obviating most of the difficulties enumerated above, there seems little excuse for continuing to use the wet colostomy by choice.

### BOWEL SEGMENT SUBSTITUTE

**Electrolyte Imbalance.** Much has been said regarding the development of electrolyte imbalance and various abnormal chemical changes due to the reabsorption of urine following uretero-intestinal anastomosis. Both large bowel and small bowel segments have had their respective proponents. It might be supposed theoretically that a large-bowel segment would absorb more because this is its normal function, but some observers have declared that there is greater absorption from an ileal segment. Lapides<sup>1</sup> on the other hand, has shown that hyperchloremia and acidosis are dependent upon the degree of kidney function rather than the degree of bowel absorption. Normal individuals given urino-onemias did not develop electrolyte imbalance because the kidneys could accommodate the greater load imposed by reabsorption, whereas patients with kidney disease did develop electrolyte imbalance after urino-onemias. This explains why some patients with uretero-intestinal implants develop electrolyte imbalance early, some late and some not at all. Patients with normal kidney function excrete the reabsorbed electrolytes and do not develop imbalance. Patients with poor kidney function due to ureteral obstruction, infection or both, develop electrolyte imbalance early. If the implantation causes improvement in the kidney function, the imbalance tends toward normal again. Patients who develop imbalance late do so because kidney function gradually deteriorates due to stenosis or infection. This concept seems to indicate that whether large or small bowel segments are used is less important than other considerations.

**Preparation of the Bowel Segment.** Two usual misconceptions must be dispelled before proceeding further with this discussion. First, there is no thought of creating a cystic retaining receptacle such as the bladder.<sup>2</sup> The isolated bowel segment is used entirely as a means of avoiding cutaneous ureterostomy and wet colostomy with their attendant complications. The bowel seg-

ment need not be large, as it never need accommodate several hundred milliliters of urine. In fact, such accumulation is undesirable. Second, there is no sphincter control of the bowel segment and no periodic emptying. Consequently, it makes little difference in which direction the peristaltic activity functions in the segment, so that reversal of the segment to slow up drainage has no advantage and may simply twist the mesentery, jeopardizing blood supply.

Ordinarily it is safe to generalize that the simplest procedure which will accomplish the desired result is the best. Therefore, it seems unnecessary to use the cecum and terminal ileum as bladder and venting tract, as advocated by Bricker and Eiseman.<sup>4</sup> This is a procedure of much greater magnitude than the circumstances usually warrant. Use of an ileal segment entails division of small bowel in two places, end to end anastomosis, closure of one end of the isolated segment, implantation of the ureters, and exteriorization of the free end of the segment. Since the rectum is being removed as part of the original operation and the large bowel must be divided anyway to form the permanent colostomy, it is simpler to avoid all of these procedures on the small bowel. We advocate use of a sigmoid segment in the following manner. The sigmoid colon is divided at a level consistent with safety from the standpoint of the tumor. The distal end then is brought to the skin surface and the sigmoid is measured for length so that it extends without tension somewhat to the right of the sacral promontory. This marks the site for division of the colon to form the distal isolated loop. The proximal point of division now becomes the colostomy stoma, the proximal end of the isolated segment is closed by inversion, and the distal end becomes the urinary stoma (fig. 1). Care must be taken to see that blood supply is not compromised, that the isolated segment is not under tension, and that it will allow implantation of the right ureter readily. The ureter must not be stripped from its bed for any appreciable distance because this interferes with its blood supply and peristaltic function. Also, the ureter must not stretch like a violin string across the peritoneal cavity to serve as a point for bowel obstruction. Finally, a clamp is left on the colostomy for from 48 to 72 hours, but the urinary stoma can be left open, with a soft catheter for sump drainage. If desired, primary application of a rubber ileostomy device is feasible and acceptable.

**Technic of Bowel Ureter Anastomosis.** Ureterosigmoid anastomosis has given poor results in the past because of obstruction and ascending infection. Many operative procedures have been devised to overcome these defects and essentially, most of them have attempted to promote obliquity of anastomosis between the ureter and bowel. It should be noted that naturally one structure

traverses the wall of another in an oblique fashion This prevents reflux and reduces the area of weakness in the wall In almost every instance where operative procedures do away with this obliquity, difficulty from reflux ascending infection or herniation result This has been the story in ureter bladder implantation in common bile duct-bowel anastomosis, and even in inguinal hernia repair Appreciation of this concept led to

Figure 1 Diagram showing anatomic relation of ureters sigmoid segment used as bladder substitute and urinary and colostomy stomata

the procedure of forming a tunnel in the sigmoid wall proximal to the point of ureteral implantation but this often led to stenosis and obstruction If the ureters are to be implanted into an isolated bowel segment without fecal stream such reflux is not a factor and obliquity therefore is not necessary in this instance Another point of difficulty has been stenosis at the stoma from failure to use mucosa to mucosa anastomosis Cordonnier<sup>1</sup> has emphasized this and his technic is advocated This consists of several interrupted fine stitches of full wall of ureter and

mucosa of sigmoid. A second layer is made by suturing serosa of sigmoid to adventitia of ureter to make a snug but not tight closure. This anastomosis must be watertight but not constricting. Such a mucosa to mucosa closure promotes accurate healing and decreases stricture formation. Finally, it should be emphasized again that one must bring bowel to ureter rather than ureter to bowel.

**Location of Stoma.** As in ileostomy for ulcerative colitis or colostomy for carcinoma, it is important to locate the stoma in such a way that bony prominences are avoided and that the bag appliances can be worn as inconspicuously as possible. This means that the lower abdominal quadrants between umbilicus and iliac crest are preferred. If a colostomy and a small bowel bladder substitute are used, symmetrical points on right and left are acceptable. However, if a sigmoid isolated segment is preferred, the urinary stoma must emerge on the left side. It seems best to make the colostomy on the left and then to place the urinary stoma sufficiently below it to allow room for the ring of the bag. This does not make too much bulk even though both stomata are in the left lower quadrant.

**Mechanics of Emptying.** Since the bowel segment is to serve as a channel for discharge of urine rather than as a retaining cavity, it is essential to see that drainage is not impeded. Necessarily, gravity is the most important factor, and with the patient upright, a not too redundant segment drains naturally. Too long a segment allows collection of urine which by its weight may obstruct the loop. It may be necessary to attach the middle of the segment to the abdominal wall but this poses a problem in obviating the loop itself as an axis about which loops of small bowel may twist. Probably, care in getting the segment of proper length is the best safeguard. Peristalsis is another factor in promoting drainage and again, since collection is not the desired end, it is not advisable to reverse the loop to slow drainage.

We recently have had occasion to do a celiotomy upon one patient, two years after exenteration. We found the ureters slightly dilated, but otherwise normal in appearance. The sigmoid segment had the appearance of normal bowel.

#### SUMMARY AND CONCLUSIONS

The possible methods of management of the ureters, assuming excision of bladder and rectum to be necessary, are cutaneous ureterostomy, wet colostomy, and bowel segment substitute. Bilateral cutaneous ureterostomy may be indicated in the seriously ill and in patients with hydro-ureter, urinary tract infection, and impaired kidney function, but is a poor                      fo                      itive

choice The wet colostomy favors serious ascending infection and obstruction of the ureter with added danger of infection and decreased kidney function and offers a much greater surface for urinary reabsorption There seems to be little occasion for its use Use of an isolated sigmoid segment is simple and obviates most of the serious complications inherent in the other methods Our personal experience embraces the various methods described, and although it has been too small to be of statistical value we prefer the isolated sigmoid segment

# CARCINOMA OF THE ESOPHAGUS

## Survival, and the Fallacy of "Early Diagnosis"

EDDY D PALMER *Lieutenant Colonel MC USA*

THE discouraging results of treatment of esophageal carcinoma are largely due to the inherent nature of the tumor, and as yet little can be done to change that. This is merely a statement of the concept of "biologic predeterminism," as emphasized by Macdonald and Kotin<sup>1</sup> in connection with the limited curability of gastric carcinoma. Almost all of those who write and advise on the subject not only emphasize the importance of early diagnosis above all else but offer it as the solution for currently unsatisfactory surgical results. It would be ideal, they say, if the first subjective hint of trouble would drive the patient to the doctor and if the doctor would then immediately suspect cancer, look for it, and find it.

During a perusal of personally observed cases of carcinoma of the esophagus, it was found that in 16 the tumor either had been discovered prior to development of symptoms or had first caused symptoms while the patient was under active medical surveillance for some unrelated disease. The present report describes experiences with these ideally "early" cases.

### DETECTION

The basic information on the 16 cases is given in table 1. In spite of the briefness of the courses, detection and identification of the esophageal disease posed no problem. There was no diagnostic delay due to smallness of the lesions. Four patients were asymptomatic as far as the esophagus and carcinoma were concerned, their tumors having been unexpectedly discovered during roentgenologic (2 patients) or esophagoscopy (2 patients) examination, carried out for study of cirrhosis, pernicious anemia, or cardiomegaly. Among the patients who developed clinical manifestations before the tumor was found, the interval between the physician's cognizance of the first manifestation and detection of the tumor amounted to no more than nine days. Nine patients were under hospital care at the time the first manifestation of esophageal cancer appeared; three were being followed closely as outpatients. In two

# CARCINOMA OF THE ESOPHAGUS

## Survival and the Folly of "Early Diagnosis"

EDWIN D. MILLER, M.D., F.R.C.P., F.R.S., F.R.C.S., F.R.C.R.

THE CARCINOMA OF THE ESOPHAGUS is a disease of the esophagus, a tube which carries food from the mouth to the stomach. It is a disease of the lining of the esophagus, and as it grows it can spread to other parts of the body. There are two main types of this cancer, one of which is called squamous cell carcinoma and the other is called adenocarcinoma. Squamous cell carcinoma is the most common type, and it is usually found in the middle and lower parts of the esophagus. Adenocarcinoma is the second most common type, and it is usually found in the upper part of the esophagus. Both types of cancer can spread to other parts of the body, and this is why it is so important to detect it as early as possible. However, the fact is that the only way to detect it is by having a test called an endoscopy, which is a procedure in which a doctor uses a special instrument to look inside the esophagus. This test is not always successful, and even if it is, it is not always possible to remove the cancer. Therefore, the only way to survive is to have the cancer removed as early as possible, and this is why it is so important to detect it as early as possible.

During a review of personally reviewed cases of carcinoma of the esophagus I was forced to conclude that the only way to detect it as early as possible is by having a test called an endoscopy, which is a procedure in which a doctor uses a special instrument to look inside the esophagus. This test is not always successful, and even if it is, it is not always possible to remove the cancer. Therefore, the only way to survive is to have the cancer removed as early as possible, and this is why it is so important to detect it as early as possible.

### DETECTION

The basic information on the 7 cases is given in Table I. In spite of the hopelessness of the disease, a search for a cure was made. The results of the search are given in Table II. There was no agreed delay in the diagnosis of the disease. Four patients were asymptomatic as far as the esophagus and carcinoma were concerned, the tumors having been unexpectedly discovered during routine gastroscopy (2 patients) or esophagoscopy (2 patients) examination carried out for a variety of reasons: pernicious anemia or cardiac disease. Among the 3 patients who developed clinical manifestations before the tumor was found, the interval between the physician's recognition of the first manifestation and detection of the tumor averaged 10 months, the longest being 18 months. Nine patients were under hospital care at the time the first manifestation of esophageal cancer appeared and they were being followed closely as outpatients. In two

Figure 2 On the first examination seven days after the first complaint of dysphagia this high degree of tumorous narrowing of the distal esophagus was found (patient 15)

#### TREATMENT

Seven patients including 3 of the 4 whose carcinoma was discovered by chance during the asymptomatic period, were considered inoperable at the time the lesion was detected. Resection was found possible in only 5 of the 9 who were

performed upon Three of the resected tumors involved the distal one third of the organ, and 2, the middle one third

Seven patients were given deep radiation therapy, as shown in the table. Personal dilatations were freely used, as indicated, but no other treatment was given. Gastrostomy eventually became necessary in one patient, in spite of dilatations

### SURVIVAL

As can be seen from the table, the courses in general were short, and the cause of death in all but patients 11 and 16 was the esophageal carcinoma. Two patients died shortly after resection. Only 4 survived a year following detection of the tumor, and only 2 were alive at the end of the second year. All but patient 9 were studied at necropsy, and it was found that at the time of death there were no gross distant metastases in 8 patients.

### COMMENT

This little series theoretically offered no favorable esophageal carcinoma material as one can hope to manage, using the currently available diagnostic approach. It is true that the co-existing disease influenced the operability rate to a certain extent, although this rate (56 per cent) was quite comparable to that observed in many large reported series.<sup>2</sup> It would not be particularly fruitful to compare the survival in this "early" group with that of the more usual type of esophageal carcinoma case. Poor results are poor results, and no encouragement for the esophageal carcinoma matter can be found in the present experience.

As long as surgical extirpation must be relied upon for hope of cure, a diagnostic approach which depends for its initiation on recognition by the patient that something is wrong is entirely inadequate. No one can doubt that early diagnosis is better than delayed diagnosis, but it is clear that by the time the first symptoms of esophageal carcinoma appear the great majority of patients are beyond surgical cure. Kiviranta<sup>3</sup> is one of the very few authors who have been realistic on this point. After studying the records of 3,756 patients who died of esophageal carcinoma in Finland, he concluded, "The life expectancy in patients subjected to treatment had no relationship whatever to the length of the symptomatic period prior to therapy. This is probably due to the fact that the tumor is as a rule diagnosed only after having reached a certain size inducing dysphagia, and the life expectancy of such patients is generally equally long, nor is radiotherapy able to affect it." This is an especially significant statement, not only because Kiviranta is an important authority but also because it shows that, when put to the test with a large number of routine cases, the concept of salvage through "early diagnosis" is meaningless.

It is not being suggested that surgical resection be abandoned as treatment, however impotent it proves for cure, because it furnishes two important palliative benefits. First, whether or not the removal of a primary tumor ever slows the growth of metastases in the case of esophageal carcinoma a remarkably large proportion of patients die from the local effects of the primary tumor itself regardless of metastases, and many die with no gross evidence of metastasis at all. Second, the most distressing subjective feature of the disease and one which in the absence of prophylactic effort is almost inevitable with long survival is esophageal occlusion. Resection of high living carcinomas is too hazardous to justify it for any purpose other than intended cure but limited distal resections when followed by peroral dilatations often prove of inestimable usefulness through preclusion of obstruction.

But it is important not to confuse little advancements with solutions. There is nothing about the present and rather unimaginative therapeutic approach to esophageal cancer to warrant more than mild interest until a better line of attack is found. Therapeutic sights must be set much higher than they are at the moment. Finding technologic means for extirpating portions of the esophagus and reestablishing continuity has clearly not solved the problem of esophageal carcinoma as far as cure is concerned. The danger is that continued effort, money, and, especially, thinking may be expended in exploring the same dead end path rather than on the obviously more productive possibilities of serodiagnosis and chemotherapy.

#### SUMMARY AND CONCLUSION

Esophageal carcinoma was detected in 16 patients either before it had produced symptoms or immediately afterward. A brief review of the therapeutic results in these patients discloses the inadequacy of "early diagnosis," as the term is now used as an answer for the discouraging problem of esophageal carcinoma. Surgical extirpation can increase the patient's comfort and perhaps his period of survival, but it proves wholly inadequate as realistic therapy. It must be concluded that to be successful long before the lesion has made its presence clinically apparent or it must be of such a nature that it will destroy cancer tissue everywhere throughout the body all at once.

# RUPTURE OF PREVIOUS CESAREAN SECTION SCAR IN SUBSEQUENT PREGNANCIES

## Report of Seven Cases

JOHN R KANE, Lieutenant MC USA

WILLIAM S HAFER Jr, Captain MC USA

**R**UPTURE of the pregnant uterus in patients previously subjected to cesarean section occurs rather infrequently. According to Brimton,<sup>1</sup> it is seen in only 3 per cent of such patients.

Opinion varies concerning the proper course to follow when confronted with the management of a patient who has had a cesarean section. Some clinics adhere to the old adage "once a cesarean always a cesarean," while others strongly advocate a trial of labor provided certain criteria are met.<sup>2-4</sup>

Concerning the best method of cesarean section, most investigators state that the lower segment procedure affords the safest prognosis, both because the scar is less likely to rupture while the corpus is enlarging during a subsequent pregnancy and because the low transverse cervical scar allows a greater margin of safety in subsequent labors, should the vaginal route be elected for delivery.<sup>1-4</sup>

Gross fetal and neonatal mortality associated with cesarean section has been reported as being higher than that associated with vaginal delivery,<sup>5</sup> and with present day improvements in management of surgical emergencies and the relative infrequency of uterine rupture, especially in lower segment scars, it may not be absolutely contraindicated to consider a trial of labor in selected cases. Schmitz and Gajewski,<sup>7</sup> Lastman,<sup>4</sup> and others<sup>1-3</sup> have reported individually regarding this problem.

The decision to employ vaginal delivery in a case with a history of cesarean section can only be made after a thorough assessment of the integrity of the scar.<sup>7</sup> The absence of tenderness and morbidity following operation does not necessarily guarantee a firm union nor complete protection from possible rupture.<sup>8</sup> The status of the uterine scar could be fairly well assessed through hysterography but this method obviously is of no help

Presented at Armed Forces Obstetrics and Gynecology Seminar 13 April 1956  
Walter Reed Army Medical Center Washington D C.

From U S Naval Hospital San Diego 34 Calif

during pregnancy. It appears, therefore, that no absolute or precise means of estimating the integrity of cesarean section scars is presently available, as is emphasized in recent publications by Watt\* and others\*

When a uterus does rupture before or during labor fetal mortality is high, as reported by several investigators. A study of fetal mortality in 1 219 cesarean sections at Tulane several years ago revealed a 5.7 per cent incidence. When all the cases were analyzed from the standpoint of indication for abdominal delivery, however, it was noted that the greatest incidence of fetal wastage occurred in the group that contained all the toxemias, placental separations, placenta previa, diabetes, and other miscellaneous complications of pregnancy. The remaining cases were uncomplicated elective repeat cesarean sections and accounted for a fetal mortality of only a little more than 1 per cent. This compares favorably with the overall incidence of fetal and neonatal mortality resultant from vaginal delivery. The fate of the infant then, as well as of the mother, is an important consideration to be resolved by the obstetrician when he considers vaginal delivery over repeat cesarean section as a routine policy.

This study critically evaluates our own past experiences concerning this problem. From an analysis of the cases reported recommendations are made as to the safest procedure for both mother and infant to follow when confronted with the alternative of performing repeat cesarean section or vaginal delivery.

The charts of all patients undergoing cesarean section at this hospital for any cause from 1 January 1949 through 31 December 1956 were analyzed from the standpoint of over all incidence of cesarean sections, total repeat cesarean sections performed, total number of uterine ruptures, and actual maternal and fetal mortality intimately associated with vaginal delivery in patients previously subjected to a cesarean section. During the period studied, there were 29 605 deliveries, of which 818 (2.8 per cent) were completed by cesarean section. The indication for operation in 499 (61.0 per cent) of the 818 patients was previous section. Ruptures of the pregnant uterus occurred in 7 (1.4 per cent) of the 499 patients in the previous section group. There were 1 maternal death and 5 fetal deaths, respectively, an incidence of 14.3 per cent and 71.4 per cent, respectively. The latter figure is in sharp contrast to the average monthly gross fetal mortality per 100 live births of 2.0 to 2.5.

The following case reports of the 7 patients with rupture of the pregnant uterus are summarized in table 1.

TABLE 1. Summary of seven cases of rupture of the pregnant uterus in patients with 1 previous cesarean section

	Case 1	Case 2	Case 3	Case 4	Case 5	Case 6	Case 7

## CASE REPORTS

**Case 1** A 34 year old white woman, gravida 2 para 1 had previously had a cesarean section at another hospital. The date and the indication for section were not known. At about the thirty-sixth week of her present pregnancy she was admitted to this hospital with a complaint of lower abdominal pain. A diagnosis of ruptured uterus was made. At laparotomy it was noted that the uterus had ruptured partially in two separate sites. A Porro-type cesarean section was carried out and the patient was successfully delivered of twin male infants both of whom lived. Convalescence was uneventful.

**Case 2** A 32 year old white woman, gravida 3 para 1 had had a cesarean section 4 years previously at another hospital. The indication was not known and the type of section was not mentioned in the operative report. The patient entered this hospital on her estimated date of confinement but was sent home as a case of false labor the following day. Five days later she was readmitted with irregular abdominal pains and was kept under observation. The next day she was examined vaginally and found to be at Station +

2 cm. The membranes were ruptured. Four hours later the fetal heart tones disappeared and bright red bleeding began. A diagnosis of ruptured uterus was made and a laparotomy was performed. The dead fetus and the placenta were found lying free in the peritoneal cavity. Supracervical hysterectomy and bilateral salpingo-oophorectomy were performed. Convalescence was uneventful.

Case 3. A 25 year-old white woman gravida 2 para 1 had had a low cervical cesarean section for premature separation of the placenta two years previously at another hospital. It was elected to give the patient a trial of labor. At 38 weeks she was admitted to the delivery room after having had mild abdominal contractions for about 10 hours. On admission contractions were 3 minutes apart and strong. Tenderness was noted in the right lower quadrant of the abdomen. Continued observation was recommended. Two hours after admission a diagnosis of ruptured uterus was made. A laparotomy was performed and a dead fetus and the placenta were found lying free in the peritoneal cavity. A midline lower segment rupture of the uterus was repaired. Convalescence was uneventful.

Case 4. A 34 year-old white woman gravida 4 para 1 had been delivered 3 years previously at another hospital by a classical type cesarean section for placenta previa. Prior to this she had had 2 vaginal deliveries. It was decided that she should have a trial of labor. At 37 weeks the patient noted sudden onset of hypogastric pain which became increasingly more severe. Physical examination revealed tenderness to the scar area. Fetal heart tones were of good quality. A diagnosis of ruptured uterus was made and a laparotomy was performed. An incomplete rupture was found in a classical scar. A living infant was delivered via a low cervical section and bilateral tubal ligation was carried out. Convalescence was uneventful.

Case 5. A 31 year-old white woman gravida 4 para 3 had been delivered 5 years previously at a hospital on Saipan via classical cesarean section "for breech presentation". At about 23 weeks of gestation the patient noted a sudden severe lancinating abdominal pain when she attempted to lift a heavy object. She was admitted in shock and after improvement in her blood pressure a laparotomy was performed. There were 2 rents in the old scar and about 1,500 to 2,000 ml of blood in the peritoneal cavity. Cesarean section followed by a supracervical hysterectomy was performed. The fetus was dead. The postoperative course was stormy. vaginal drainage of a pelvic abscess and incision and drainage of a subdiaphragmatic abscess had to be carried out. The patient was discharged after 48 days of hospitalization.

Case 6. A 33 year-old white woman gravida 2 para 1 had had a delivery by abdominal hysterectomy at 6½ months gestation at another hospital 4 years previously. The indication was unknown. The present pregnancy was uneventful until 30 weeks when the patient entered

the hospital with a complaint of nausea, vomiting, and abdominal pain for the preceding 48 hours. The preoperative diagnosis was ruptured uterus with small bowel obstruction incident to hemolytic irritation of the peritoneum. At laparotomy it was noted that the uterus had ruptured along a classical cesarean section scar and that a dead fetus and the placenta were lying free in the peritoneal cavity. A total hysterectomy was performed. Postoperatively the patient suffered a wound dehiscence that required secondary closure.

**Case 7.** A 40-year-old white woman, para 7, gravida 3, abortion 3 had been delivered 2 years previously at this hospital via a low cervical cesarean section for central placenta previa. The present pregnancy was complicated at about 32 weeks' gestation by vaginal bleeding and ruptured membranes. Because the baby was premature the preceding cesarean section had been performed at this hospital, and conditions were considered ideal for the procedure vaginal delivery was elected. After 75 minutes of labor, during which a small amount of bleeding was noted, the patient was delivered via low forceps under pudendal block and anesthesia. During delivery vaginal hemorrhage became profuse. The infant's condition was critical at birth and it died shortly afterward in the nursery.

The placenta was manually removed and exploration of the uterine cavity revealed adherent placental fragments in the cornual area. The previous section scar was thought to be intact. Because the patient had bled so profusely and shock had occurred, the uterus was packed and transfusions were expedited; however, when the blood pressure rose, bleeding again became profuse. After 2 hours of this heroic type of treatment, a laparotomy was performed. No blood was found in the peritoneal cavity, but there was a tear in the lower uterine segment in the region of a lower segment scar near the uterine bundle and the cardinal ligament on the left. A total hysterectomy was performed.

After the operation the patient responded briefly, then commenced bleeding from orifices and mucosal surfaces. Despite more blood transfusions and fibrinogen therapy she died 4 hours later.

#### FETAL AND MATERNAL MORTALITY

As mentioned previously, rupture of the pregnant uterus carries with it an increased incidence of fetal mortality. Table 2 which lists pertinent statistics from this hospital and several other institutions, shows that we have the highest fetal mortality and second highest maternal mortality directly attributable to rupture of the pregnant uterus. This situation would, at first, seem to be a direct result of the policy followed at this hospital of vaginal delivery in selected cases of previous cesarean section. Close study of table 1, however, will not substantiate this interpretation. Only 3 patients out of the 7 were allowed to go into labor, and only 1 was delivered electively by the vaginal

route. Our single maternal death did, however, occur in the 1 case allowed to deliver vaginally. Perhaps this would decisively influence our thinking concerning the problem of repeat section versus vaginal delivery were it not for the fact that during the period studied several carefully selected patients who had had previous cesarean sections were safely delivered vaginally in our hospital.

#### DISCUSSION

Many investigators have emphasized the increased safety and decreased danger in performing cesarean section in recent years

" The mortality of cesarean section has been reported by several large obstetrical centers to be in the neighborhood of 0.3 per cent.<sup>11</sup> We must remember, however, that 200 maternal deaths a year in the United States are attributed to rupture of the uterus.<sup>12</sup> Brierton<sup>1</sup> reported that 50 per cent of uterine ruptures occurred in the scars of previous sections, of the remainder, 20 per cent were incident to trauma during obstetrical manipulation and 30 per cent were recorded as miscellaneous etiology. Harris<sup>13</sup> reported a maternal mortality incidence of 0 to 11 per cent in the series of Schmitz and McInne. In our own series we sustained 1 maternal death in 7 ruptures, an incidence of 14 per cent (table 2).

Letal mortality associated with rupture of the uterus is exceptionally high, 71 per cent occurred in our own series. The incidence of uterine rupture averages about 1 per cent in women who have had a previous cesarean section. The relative safety of the low cervical operation, which is supported by most obstetricians,<sup>14</sup> is probably open to question, as there is no fool-proof method available to assess the strength or integrity of the scar. This fact must be known if delivery is to be safely accomplished through the vagina.

On the other hand, maternal mortality in the elective cesarean section patient statistically approaches that of vaginal delivery.<sup>15, 16</sup> Letal mortality associated with elective cesarean section and corrected for the complications of pregnancy that do not necessarily attend such an elective section, approaches that of fetal mortality accompanying vaginal deliveries.<sup>17</sup>

In view of the evidence collected, we believe that a trial of labor in the case of a woman who has had a previous cesarean section is definitely a gamble and should not be attempted unless the following criteria can be satisfied: (1) there is no demonstrable cephalopelvic disproportion, (2) the previous cesarean section was of the low transverse segment type, (3) there was no morbidity following the previous section, (4) there is no malpresentation in the present pregnancy, (5) there is no demonstrable scar tenderness, (6) the patient will be attended by an obstetrician throughout her labor, (7) sufficient blood will be available for instant use if required for transfusion, (8) an operating room and team will be available in the event of rupture, and (9) the patient thoroughly understands and accepts the added risk involved. This leads to the inevitable conclusion that the safest method of delivery for the previously sectioned patient is by low transverse cervical cesarean section near term.

#### SUMMARY AND CONCLUSIONS

Analysis of 29,605 deliveries in this hospital during an 8 year period showed 7 cases of obstetrical rupture of the uterus

following previous cesarean section, with 1 maternal death and 5 fetal deaths

Review of the literature reveals considerable frequency of uterine rupture and of related fetal and maternal mortality

A margin of safety is afforded both mother and child by present-day cesarean section whereas important criteria must be satisfied prior to carrying out vaginal delivery in a previously sectioned patient and methods of evaluating the scar for a trial of labor are far from satisfactory

Repeat cesarean section near term is strongly recommended as a routine obstetrical policy in the majority of cases

# RADIATION HAZARDS AND MEDICAL X RAY PROTECTION

In Installations of the U S Army, Europe

PAUL A PADEN Colonel MC USA

**T**HE HAZARDS of ionizing radiations, in general, and those attendant to many routine x ray procedures, in particular, have only recently been receiving the consideration they deserve. Laymen, as well as most doctors and dentists, still do not fully appreciate these hazards. Through the years many radiologists and x ray technicians have ignored sound principles of safety. They have lived to regret it. At the Saint George Hospital in Hamburg, Germany, there is a monument in memory of persons known to have died through use of roentgen rays. One hundred ninety nine names are inscribed, and at least three more remain to be added.

## RADIATION AND LEUKEMIA

It is only in the incidence of leukemia<sup>1</sup> that the effect of small quantities of radiation have to any extent been adequately studied. The incidence of this disease is almost twice as great in physicians as in the general adult population, and the incidence in radiologists is over nine times as great as in non radiologic doctors. The increase in incidence in physicians results mainly from the inclusion of radiologists in the statistics, when they are excluded, the slight increase may well be accounted for by the non radiologists who use fluoroscopes, x ray machines, radium or radioactive isotopes. A study of the causes of death in dentists, x ray technicians and others using x ray or radioactive materials would probably show similar startling statistics.

## INCREASE IN RADIATION !

The ever increasing use of x rays in therapy, to say nothing of the use of

a source of power and in the manufacture and testing of nuclear weapons—with the attendant accumulation of waste material and the effects of fallout—are rapidly increasing the radiation hazard and distributing it to the general population. The possible genetic effects on human beings of large doses of radiation are being carefully studied but the results will not be known for several generations. There is increasing evidence, however, to justify the warnings of many careful observers that the irradiation of members of one generation will cause genetic damage in future generations.

The effects of radiation are often extremely slow in becoming manifest. Changes in the skin of a person's face resulting from small accurately measured doses of radiation used in the treatment of acne may not appear for ten or fifteen years. The painful rodent cancer on the hand of an x ray machine repairman who occasionally uses that member for testing may not occur for many years after the last exposure. One of the "American Martyrs to Science through the Roentgen Rays," Dr William Krauss died as a result of malignant changes occurring in the skin of his fingers which had been damaged by exposure to x rays thirty eight years before. At the age of fifteen a boy developed a marked varus deformity of the left knee, from which a foreign body had been removed fluoroscopically ten years before.

The known dangers of fitting shoes by x ray have recently begun to receive proper attention. The time it takes for one person to check the fit of shoes by a glance through the x ray machine is not long enough to present a radiation hazard even at the close distance and at the high milliamperages required for unadapted eyes. Usually, however, if a child is being fitted, he and his parents as well as any brothers and sisters present, in addition to the salesman must see the fitting. The number of feet which have been permanently damaged because of use of those x ray shoe fitting machines will never be known since changes are bilateral and may be attributed to other causes. Many of our own states have wisely regulated the use of these machines or banned them altogether.

#### X RAY UNITS IN USAREUR

There are well over 100 U S Army diagnostic x ray installations and many dental x ray units in operation in USAREUR medical and dental facilities. Less than one half of the medical x ray units are under the constant supervision of a trained radiologist. While many of these x ray units are well screened and safely operated others are hazardous especially to the operators. Screens with no lead glass or with push buttons which are on the dangerous side\* of the screen are examples. In one

heavily loaded installation, when the x ray machine was operated, 50 mr/hr were reaching the personnel in the laboratory across the hall

Dental x ray units are particularly hazardous to the operators and to the occupants of surrounding areas unless shielding is adequate. These units are small and innocent in appearance but are really wolves in sheep's clothing. Because of their very short focal film distances and long exposure times, their use for a full mouth x ray with no filter and with retakes required may expose the patient's face to an erythema dose. The x ray beams reach not only the teeth, in addition, the neck tissues with their abundant lymphatics receive heavy doses. Depending on whether or not filters are used and also dependent on the distance, roentgens delivered may vary from 40-270/min<sup>2</sup>. With the latter higher rate one machine delivered 315 r during a routine full mouth examination without repeat films. For this quality radiation 350 r is considered an erythema dose.

For all diagnostic procedures, particularly for dental x rays and fluoroscopy, external aluminum filters must be employed, 1 mm for radiography and at least 2 mm for fluoroscopy.

### HAZARDOUS FLUOROSCOPIC AND X RAY PROCEDURES

Many fluoroscopic and x ray procedures are hazardous and must receive careful consideration at all times.

1 *Examinations of the abdomen or pelvis during early pregnancy* Be sure that the patient is not pregnant before you order lumbar spine films, a GI series, a barium enema, an IVP or fluoroscopic examination of the abdomen.

2 *Multiple films of the abdomen at any time during pregnancy* Routine pelvimetry by the use of multiple films is of questionable value and may be fraught with danger to succeeding generations, because the examination may need to be repeated to secure adequate information. If there is definite evidence of pelvic deformity by measurement, pelvimetry may be indicated, but its value remains questionable in view of the non visualized soft tissues. If done, the procedure should be reserved for late pregnancy.

#### 3 *Repeated full-mouth dental x-rays*

4 *Repeated examinations of a part of the body, over a period of days, or on a single day during surgery, e. g., a fracture of the femur for position of the fragments during and after nailing.* I am sure many of you have removed a cast and noted that the skin was tanned and peeling. How many have seen this? Why the skin would tan while covered by cast?

- 5 Prolonged fluoroscopic procedures of any nature, particularly with the patient remaining in the same position
- 6 Most hazardous to both patient and doctor is the setting of fractures or attempted removal of foreign bodies under fluoroscopic control These should not be attempted During World War II, in one Service Command alone at least three Army physicians lost fingers and may later die from a one time performance of such procedures

### SAFETY STANDARDS FOR PERSONNEL AND EQUIPMENT

Personnel engaged in x ray work must follow safe practices at all times equipment must be known to be safe, and shielding must be adequate All diagnostic equipment must be operated only under the supervision of a medical or dental officer whose duties and responsibilities are clearly defined and outlined in TB Med 62 In general this bulletin sets up those requirements

1 Equipment must be safe and shielding must be adequate Shielding present may not equal or may exceed the requirements of TB Med 62, but it must be safe Stone, cement plaster and/or lead in adequate quantity are equally efficacious for shielding The shielding requirements of TB Med 62 are ideal, are based on Handbook 41 "Medical X Ray Protection Up to Two Million Volts" and are designed for use in new construction Theoretical ly all departments should meet these requirements, all new construction must The Surgeon General and/or the Department of the Army have usually granted relief for old installations when they are found by survey to be safe The requirements in TB Med 62 are designed to insure that the dose presently considered safe, 3 r per week is not exceeded This rate may be further reduced to 6.25 mr/hr or 104 mr/min for a 48 hour work week with full time work

2 A health folder must be maintained for each individual exposed to x radiation Into this folder must go

a The physical examination record and history report on the person when he starts work in the department, including a chest film report records of follow up examinations made yearly

b A copy of initial blood counts performed at a stated hour on at least two successive days with repeat examinations if indicated

c Copies of blood counts at three or six month intervals, dependent on whether or not monitoring is practiced afterward It is of utmost importance in the case of military personnel that a copy of all blood counts be placed in their permanent 201 files for future reference particularly the repeated original blood

counts made when they started as a radiologic test of a ray technician. Repeated routine blood counts are not all important if continuous monitoring is practiced and a detailed permanent record maintained.

d A statement that the person has read and understands the safety rules of the department.

e A record of the exposure the person has received as indicated by a monitoring chamber or by actual dental films of chest tests showing doses film was worn.

f A copy of the chest film report of the person at 6 month intervals.

g Safety rules must be posted and adhered to. All personnel must understand them.

The following safety rules are used at the U. S. Army Hospital, Neuhrucke, and are considered sufficiently detailed. They may be expanded when desired.

## RULES FOR SAFE OPERATION OF X-RAY EQUIPMENT

### 1 Operation of Radiographic Apparatus

a A competent operator shall be at the control during any radiographic exposure.

b When it is necessary to hold the patient during the exposure no person shall be regularly employed, nor shall anyone from the department of radiology be permitted to perform such service. The person holding the patient should wear lead protective gloves and a lead protective apron. No part of this person's body shall be in the useful beam.

c No persons other than the patient and those needed to hold the patient shall be in the radiographic room during exposure.

d Radiographic work shall be performed with the smallest field consistent with clinical requirements. Always use cones or diaphragms.

e All technicians will insure themselves that they are never outside the control booth when an exposure is made unless they are wearing a lead apron and are as far as possible from the tube and patient. *This method of operation will be tolerated only for special procedures such as angiocardiology and cerebral angiography.*

## 2 Operation of Mobile Apparatus

a The technician *shall* stand as far as possible from the tube and patient during exposure and *shall not* stand in the useful beam

b An operator standing at least 6 feet from the tube and patient should not make more than 15 000 milliamperes seconds of exposure during any one week. This corresponds approximately to the weekly permissible dose. Rotation of operators or wearing of lead protective aprons is required for longer exposures. For his own protection the technician *should always wear a lead rubber apron*

## 3 Operation of Fluoroscopic Apparatus

The fluoroscopic equipment *shall* be operated only by a medical officer of the department of radiology or by a medical officer authorized by the radiologist in charge to conduct fluoroscopic examinations

a The fluoroscopist should have completely dark adapted eyes before proceeding with a fluoroscopic examination

b Fluoroscopic examinations *shall* be performed in the minimum time possible using the lowest x ray intensity and smallest aperture consistent with clinical requirements

c Lead protective aprons *shall* be worn by the medical officer technicians and all other personnel within the fluoroscopic room

d Lead protective gloves *should* be worn during every examination

e The hand of the fluoroscopist either with or without gloves *should never be* placed in the useful beam of radiation

## 4 Operation of Therapeutic Apparatus

a Only the patient *shall* be in the treatment room during exposure except when it is necessary to hold the patient as in the case of small children. No members of the radiological staff or other persons normally near x ray equipment or radio active materials *shall* hold the patient during irradiation. The person holding the patient *shall not* be in the useful beam and *shall* be protected as much as practicable from scattered radiation

b The patient and x ray control *shall* be under observation during exposure

c The useful beam *should* be directed toward unoccupied regions if consistent with therapeutic requirements

4 Maximum permissible exposures must not be exceeded as stated in tables in TB Med 62. It is the responsibility of the doctor or dentist to know the requirements of this directive and to satisfy himself that they are complied with.

To check how safe an installation is from the standpoint of radiation hazards, dental x ray film with paper clips or lead numbers attached may be left for one week on all areas presumed to be safe and then developed. An outline of the clip or letter or any blacking of the film indicates an unsafe condition requiring immediate correction. Obvious lack of shielding should be corrected locally. If doubt still remains as to safe conditions, the Maintenance Section, Rhine Medical Depot, should be requested to perform a radiation survey. They do not at present have adequate personnel or equipment to make routine surveys of all x ray installations.

#### The Ionization Chamber

AR 40 414<sup>a</sup> requires continuous personnel monitoring of x ray personnel by ionization chamber. Chambers and chargers are now available as Signal issue items in accordance with Change No. 1, USAREUR Circular No. 720-5, "Allowances of Supplies and Equipment," dated 21 September 1955. Batteries, BA 51 (67 1/2 volts) and BA 30 (1 1/2 volts) are required for use of the chargers, and if they are not available, they should be requisitioned simultaneously. Difficulty may be experienced with the chargers because of damage in shipment. A small wire loop switch connected to the charging button is the usual source of trouble, causing the central electrode to receive continuously charging current regardless of whether or not the charging button is depressed. Instructional material accompanying the chargers and chambers is complete and informative. It must be thoroughly understood before the instruments are used. The chambers are usually very stable with regard to leakage, and readings as a rule will not be required more often than once each two weeks after it has been determined by more frequent readings that personnel are following safe practices. High readings may occur if safe practices are dropped. Until chambers are in use, a dental film as described above can serve as a rough estimate of the radiation personnel are receiving. For the technician, there should be no blackening, for a fluoroscopist, a faint outline of the clip or letter in a week is allowed, but he should review his procedures.

#### SUMMARY

- 1 Some diagnostic x ray procedures are hazardous.
- 2 Every precaution must be taken to reduce such procedures to a minimum.

## 2 Operation of Mobile Apparatus

a The technician *should* stand as far as possible from the tube and patient during exposure and *shall not* stand in the useful beam

b An operator standing at least 6 feet from the tube and patient should not make more than 15 000 milliampere second of exposure during any one week This corresponds approximately to the weekly permissible dose Rotation of operators or wearing of lead protective aprons is required for longer exposures For his own protection the technician *should always wear a lead rubber apron*

## 3 Operation of Fluoroscopic Apparatus

The fluoroscopic equipment *shall* be operated only by a medical officer of the department of radiology or by a medical officer authorized by the radiologist in charge to conduct fluoroscopic examinations

a The fluoroscopist should have completely dark adapted eyes before proceeding with a fluoroscopic examination

b Fluoroscopic examinations *shall* be performed in the minimum time possible, using the lowest x ray intensity and smallest aperture consistent with clinical requirements

c Lead protective aprons *shall* be worn by the medical officer, technicians and all other personnel within the fluoroscopic room

d Lead protective gloves *should* be worn during every examination

e The hand of the fluoroscopist either with or without gloves *should never be* placed in the useful beam of radiation

## 4 Operation of Therapeutic Apparatus

a Only the patient *shall* be in the treatment room during exposure except when it is necessary to hold the patient, in the case of small children No members of the radiological or other persons normally near x ray equipment or radio materials *shall* hold the patient during irradiation The person holding the patient *shall not* be in the useful beam and *shall* be protected as much as practicable from scattered radiation

b The patient and x ray control *shall* be under observation during exposure

c The useful beam *should* be directed toward unoccupied regions if consistent with therapeutic requirements

# DEVELOPMENT OF A THERAPEUTIC COMMUNITY

## Problems Encountered In Daily Community Meetings

FRANK L. RUNDLE *Lieutenant, VC USNR*  
DENNIE I. BRIGGS *Lieutenant, USN*

**I**N A previous article,<sup>1</sup> we dealt with the initial problems encountered in the operational transition of a closed psychiatric ward in an overseas naval hospital from traditional management methods to those embodied in the concept of the therapeutic community as developed by Jones<sup>2</sup> and Wilmer.<sup>3,4</sup> About 6 weeks after the program was initiated, the previously described daily group discussions on the closed ward were extended to include the entire service. The size of the group meetings after the open ward was added reached a maximum of 120 patients and staff.

For several weeks, developments were satisfactory and encouraging, and then a series of incidents occurred that necessitated dividing the community into two separate parts, the closed and open wards. The most important factors involved in this disorganization were the marked heterogeneity of the patient population, premature relaxation of some of the former closed ward restrictions, and a lack of adequate communication between members of the staff and between staff and patients. After about three months it was again possible to establish the service as a total community, and it has been operating as such since that time.

One of the most important results of the adoption of the community method has been the elimination on the closed ward of all forms of mechanical restraint, including seclusion rooms. These have been used during the past five months only for segregation of disturbed drunk patients. The use of sedation on both wards is now rarely necessary, and the ataractic drugs are used only occasionally to control severely anxious and disturbed individuals.

Currently all patients and staff meet for 45 minutes 4 times a week for the community group meeting. Following a 15-

---

From U. S. Naval Hospital, Yokosuka, Japan. Dr. Rundle is now at the New York Clinic, New York Hospital, 525 E. 68th St., New York, N. Y.

meeting, the staff meets to bring together all information available about patients and to discuss the meeting just held. Subsequent to that the closed ward patients meet with the ward corpsmen for a second group discussion. In addition many open ward patients are assigned to small therapy groups, these being led by the nurse and senior corpsman, under supervision of the medical officers. A few patients are given individual psychotherapy, but the treatment for most is almost entirely within the community setting. In addition to the meetings described, the closed ward staff meets early each morning to exchange information and observations, and one afternoon weekly the entire staff meets in a group designed primarily for working out staff interpersonal difficulties.

During the period covered by this article, a number of problems arose repeatedly. They will be presented here, together with some of the methods developed to deal with them.

### PROBLEMS OFTEN ENCOUNTERED IN COMMUNITY MEETINGS

**Here and Now Problems.** Jones<sup>2</sup> and Wilmer<sup>2</sup> have pointed out that often the most important material for treatment is contained in day by day behavior and the feelings involved in interpersonal relationships. Initially the importance of dealing with these obvious factors was overlooked, instead, patients were encouraged to reveal and discuss deep inner feelings and ideas. As a result many opportunities that arose in the frequent interpersonal difficulties were lost. When it became clear that this was the case, the emphasis was shifted and all members of the community were encouraged to bring up the small aggravations, annoyances, tensions and resentments that arose within the community. In many cases this led to discussion and working through of underlying personal problems even though they were not primarily emphasized.

**Naming Names.** In this community there has been extreme reluctance to reveal names of persons discussed, when the behavior involved was in any way antisocial, unacceptable, or could be considered an offense under military law. For instance a patient may bring up in the group meeting, "There's a patient drinking on the ward, I'm not saying who it is but..." In such a case he would be interrupted and asked to name the person about whom he was talking. If he refused he would be discouraged from continuing unless the person involved should speak up. If the person did not speak up the group would be asked whether anyone could assist in determining who was being discussed. If this failed the matter would be allowed to drop even though it would seem important that the issue be settled. The exposure of antisocial behavior before the group usually causes embarrassment and discomfort in the individual concerned and resentment to-

ward him by his peers. These factors constitute social pressure, which if handled properly may be used effectively to bring about alterations in behavior patterns. If names are not revealed, this pressure cannot be usefully employed. The staff is also required to identify persons discussed, and many times the patients will call their attention to the need to do so.

Another reason it is believed necessary to name names is to prevent introduction to the group of factually inaccurate information. On one occasion, a 17 year old youth with a basically schizophrenic make-up, whose constant acting out was provocative and designed to arouse hostilities between patients and staff, asked what would be done if it were learned that narcotics were being brought on the ward. At that time it was not insisted that he make clear what he meant and name those involved, the discussion continued on a hypothetical level, and three patients who were under investigation for narcotics use became extremely angry and disturbed as they believed that suspicion was being cast upon them. Other patients seemed to become angry and anxious about the situation, and it was only after several meetings that all the feelings and tensions had been worked through and the facts of the matter established. Most of the difficulty could have been avoided had the person who introduced the subject been forced to name names or admit that he had no reason to think that narcotics had actually been brought on the ward.

Patients often took the attitude that informing on persons involved in illegal activities would be "squealing" or "ratting" and that this would disrupt friendships and social standing on the ward. Sometimes patients openly interfered with the efforts of the staff to encourage the revealing of such information. In such instances, the staff pointed out that withholding information which aided another to escape detection of antisocial behavior was not helping him in terms of real treatment, which was the object of his hospitalization. Occasionally the example was cited by staff or patients of a patient who a few months before went AWOL and later was found dead of an overdose of heroin. Many patients on the ward knew that he was going AWOL and, in fact, some co-operated with him, but none had alerted the staff. In this instance it was clear that had someone "squealed" it would have been a worthy and constructive action.

When the person named in cases involving socially unacceptable behavior is a member of the hospital staff, it is important to have that person present even though he is not a member of the psychiatric staff. In some instances, staff personnel from other departments, such as the master-at-arms staff, who were named by patients as having been involved, were invited to attend the group meeting, with beneficial results for the com-

munity and for themselves. In some cases the person named was in such a position that it was impossible to obtain his presence at the discussion; this was one of the disadvantages that was inherent and unalterable and hence had to be accepted.

**Confessions.** It was found that it often was unwise to allow patients to be "pressured" by the group into discussing a matter of deep personal concern that would be in the nature of a confession, because it would make the person liable to legal proceedings. This problem arose chiefly in connection with sexual matters that under the Uniform Code of Military Justice are illegal, particularly homosexuality and other perversions. In this military setting it was found that it was impossible to deal with such matters therapeutically because of legal and administrative attitudes as well as the secondary attitudes that arose from them. In a few instances in which group pressure resulted in confession of material that could not be adequately worked out, the effect on the person involved and the group as a whole was considered to be detrimental. If a staff member realized that a patient was being pushed toward revelation of such personal, highly charged emotional material, the process was interrupted directly.

**Legal Entanglements.** Related to the problem of naming names and handling confessions was that of what action to take when cases of infraction or violation of laws or regulations arose in the group meetings. The social pressures operative within the therapeutic community were such as sometimes to cause information to be revealed that could lead to legal action and punishment. This arose most frequently in instances of drinking or gambling in the hospital, going AWOL, and financial indebtedness to other patients. In such cases the decision was made individually as to whether taking legal action would be beneficial in terms of conscience development or relief of guilt.

Sometimes the decision as to whether legal action should be taken was influenced by the manner in which the community responded to the situation. It was interesting to see how emphasis on honesty and truthfulness and conformity to social rules and customs sometimes promoted the acceptance of such qualities by patients. Often patients would seek private interviews to reveal their own infractions of rules, knowing full well that to do so was to invite legal action. In the community, it was emphasized that members must face their social responsibilities to the group and that they should not seek to escape punishment by private revelation of guilt. Sometimes patients on the eve of their departure from the hospital would confess to having committed some illegal act, stating that they just could not leave without "getting it off their chest." On occasion they offered con-

crete suggestions as to how we could help other patients who engaged in such behavior, usually indicating that they believed the staff's attitudes to be too lenient.

**Antisocial Behavior.** Situations which were indications for legal action have been discussed, but in the therapeutic community problems constantly arose that involved antisocial behavior of a nature which would not justify formal legal action. Examples of such behavior were failing to observe reveille, refusal to perform work details, making noise after taps, and using the property of others without permission. Such matters, although they seem minor, often led to intense friction and hence were the subject of discussion in the large group meetings.

When such behavior was discussed, the offender was first asked if he could explain his actions to the group, then the group was asked to express opinions and feelings. Patients and staff have indicated many times that on occasion they had conformed to rules and social expectations because they dreaded having their actions examined and discussed by the group.

There were certain situations involving antisocial behavior that consistently caused considerable tension and tended to disrupt the community, hence the rules and social requirements were strictly enforced. Examples of such situations were nonattendance at group meetings, gambling, consumption of alcohol within the hospital, and borrowing money. When possible these matters were dealt with within the community, but in some cases legal action was taken. On one occasion a patient was placed on report for deliberately evading attendance of group meetings despite repeated warnings, for this, and the fact that he lied when he appeared at Captain's Mast, he was awarded a court-martial. At that time this action seemed drastic, but in the long run the effect was beneficial to the community and to the patient.

Occasionally antisocial behavior of a staff member on or off the psychiatric service was discussed in the group meetings. In such cases the situation was handled no differently than if it were a patient who was involved, so as to make it clear to staff and patients that the staff as well as the patients were expected to conform to community rules and customs. Once a staff corpsman from another hospital department aided a psychiatric patient in going AWOL and also borrowed money from him. This staff man was invited to attend the group meeting and was asked for an explanation. The patients in general tended to excuse and defend him, but the outcome was that he was placed on report and legal action was initiated.

One of the greatest difficulties in regard to the problem of minor acting out by patients was a lack of consistency among

the staff corpsmen in enforcing rules. For the most part this has been overcome by an active teaching program and frequent staff meetings wherein efforts are constantly made to maintain open communication among the staff. Another problem was that the staff corpsmen were reluctant to introduce to the group information concerning relatively minor antisocial behavior by patients or staff. They seemed to feel that such things were not important enough to warrant the group's consideration. Also at first there seemed to be an attitude that this would be "squealing." This problem was gradually overcome as the staff became educated and experienced and felt secure in their position in the community.

Recently it seemed that in the group discussions too much emphasis was being placed on the misbehavior of patients which led to the attitude among many of the patients that they were being "placed on trial." In retrospect it appeared that the approach was too moralistic without sufficient effort to understand why such behavior occurred. When this was realized, a deliberate attempt was made to shift the emphasis. At present it cannot be said which approach was the more useful in the operation of this particular therapeutic community.

**The Indefinite Answer** Sometimes patients indicated in the group meetings that they were angry with or disappointed in the staff because questions or issues were not squarely met and answered or settled. In general questions directed to the staff were reflected back to the person asking them or were passed on to the group, as often a question was asked primarily as an opening for discussion rather than to obtain a direct answer. Sometimes it was necessary to answer a question directly and concretely. This was so especially with questions concerning psychiatric illnesses, diagnoses, theories and treatment. In such cases a simple, honest, direct answer was useful in educating patients, in clarifying misconceptions in allaying anxiety and in removing the shroud of mystery that so often surrounds such matters.

When a question discussed in a meeting appeared not to have been adequately answered a staff member would state the issue, summarize the discussion and give an explanation or answer if possible. If none was possible he would say so plainly. Often patients remarked "Why not just say there is no answer, rather than beat around the bush?"

**Only the Doctor Can Help Me** An opinion frequently expressed in the discussions was that because most of the group were patients and had problems of their own it would be futile to introduce personal problems to the group for their consideration and assistance. Another phase of that attitude was the belief held by most

patients when they came to the hospital, that any help must come from the doctor himself. To many, being a patient involved passively co-operating with the doctor's orders in the hope that relief from distressing symptoms would ensue. Perhaps this procedure would work in some aspects of medical or surgical treatment, but in psychiatry it would be inimical to the treatment process.

When a patient in the meeting brought up his feeling that only the doctor could help him, several approaches were utilized. Obviously there were occasions when the reality situation was such that only individual psychotherapeutic treatment could be expected to give relief, and this was arranged for when possible. In other cases, in which it was believed that the therapeutic community effect would be beneficial, the approach was designed to aid the person in understanding how the community operated and what could be expected if he entered into it. One way of dealing with the problem was for one of the doctors present to call attention to his presence and that of other doctors, and to point out that they were there to help in any way they could. Another approach was to make a simple statement that in the past it had been found that patients could be of great help to other patients. Sometimes it was pointed out that in cases involving difficulties in getting along with people, working them out with the doctor alone would not necessarily ensure that the solutions could be applied outside the individual therapeutic setting. It was pointed out that in some cases the working through of such difficulties in a large group would be more beneficial. Often, patients who had been in the hospital for some time gave "testimonials" that they actually did receive benefit and assistance from other patient members of the group.

From the beginning a deliberate attempt has been made to foster the attitude that patients, as members of the community, have responsibilities in the treatment of other patients. This attitude was developed and perpetuated only by constant and persistent efforts by the staff. An example of a way in which patients shared with the staff in the treatment of a patient was that of a career Navy man who had made a nearly successful suicidal attempt. On the closed ward, under the unobtrusive supervision of the staff, the patients stood "special watches" over him and aided in his nursing care. Later, when this patient was ready for transfer to the open ward, he requested that he be allowed to remain on the closed ward in order that he might share in the treatment of more seriously ill patients and thus discharge his "debt" to the community and show his gratitude to the group. Following extensive surgical repairs and physical therapy, this patient was restored to full duty.

An important part of functioning of the therapeutic community as developed here was that the patients shared directly with the staff the responsibility for care of psychotic patients, especially those who were seriously disorganized. Several patients who were confused, disoriented, agitated, hallucinating, and delusional were cared for by patients in co-operation with the staff in such a manner that these patients were never left alone except when they slept. In some cases, catatonics were "forced" to leave their beds, play games, eat meals, take showers, and shave, through the efforts of the group. They were never abandoned to their private autistic worlds of fantasy, hallucinations, or delusion. They were faced with reality nearly 24 hours daily which included their being drawn into social relationships, both individual and group. Sometimes disorganized patients during lucid intervals would adopt this helpful attitude toward others who at the moment were less well than they. In several instances, acutely schizophrenic patients showed dramatic improvement after 2 or 3 days of such treatment. Such improvement not having been observed prior to institution of therapeutic community methods. Of course there were other schizophrenic patients who did not improve. Because of the short time period involved and the lack of follow up information on these patients, it is impossible to draw any conclusions as to the efficacy of this treatment in terms of the over all disease process. It is believed, however, that because this treatment was begun within hours or days of an acute psychotic disorganization with at least interruption of the disease process, the likelihood of its having permanent beneficial effect would be great.

The limitations of community means of treatment are realized, in that emphasis is on social recovery rather than on personality reorganization. However, if the means to do individual interpretive psychotherapy are not available, social recovery is an important achievement and may have equally ambitious goals.

**There's Nothing Wrong With Me** Inasmuch as the majority of patients with whom this article deals were admitted to the hospital not because of their own request for aid but because of personal external circumstances, there were many who maintained the attitude that there was nothing wrong with them and that they should not be in the hospital. This was in fact true of some patients and they were returned to duty as soon as possible. Those who were retained despite their belief that it was unnecessary were particularly resistant to acculturation into the therapeutic community and often attempted to disrupt the group discussions with their insistence that they were perfectly well and should not be in the hospital. This situation was usually recognized by other patients who had been in the community for some time and were

quite skilled at uncovering and pointing out denials, inconsistencies, and rationalizations. When the group did not do this spontaneously, a staff member posed the question, "Does anyone see any reason why this man should be in the hospital?" This usually was sufficient to start the process of dealing with the man's resistances. One of the most effective functions of the community was in demonstrating to nonpsychotics that internal factors often were more responsible for their maladjustment than the external factors they frequently blamed. The psychotic patients who used paranoid thinking presented somewhat the same problem, and in many cases they responded to group processes in such a way that their paranoid systems were either modified or more narrowly delimited. The other patients soon recognized that such persons were very ill, and responded to the staff's requests for assistance in defining reality to them.

**Sharing of Feelings by Staff** One of the most difficult problems encountered and one which still remains is that of the staff's reluctance to share their feelings with patients and with each other. It is difficult to know just how much personal information and feelings staff members should reveal in group discussions. In general it is believed that any feelings that, when unexpressed, interfere with any phase of community functioning or relationships should be openly discussed if the occasion arises. Initially, it seemed that the ward corpsmen were reluctant to follow this course, because they saw in it an obliteration of the distinctions between them and the patients. The natural extension of their thought was that they themselves might be considered to be mentally or emotionally ill.

It is not possible in the therapeutic community for the feelings and behavior of any member, including the staff, to be immune from scrutiny, because all are interrelated. This problem has been stated by Jones:

If the concept of free communication and analysis of current tensions is implicit in the treatment ideology of a therapeutic community, it is difficult to see how the staff can escape the need to face this challenge. A distinction is sometimes made between what is relevant to the treatment situation and what pertains to the individual's private life.<sup>4</sup>

It is not believed that this aspect of this community's functioning has yet been worked out satisfactorily. Recently a change was instituted to require all available staff members to attend all large group meetings and all staff conferences, and it is believed that this was a step in the right direction. Daily staff meetings following the large group meeting are still held in addition the closed ward staff meets early in

a weekly meeting has been established in which staff members are encouraged and in fact urged to express their feelings about each other freely or about patients if the feelings constitute a hindrance in their dealings within the community. Progress has been slow insofar as staff members freely expressing feelings about each other is concerned. In general it is believed that such an approach is necessary. Recently in a meeting one of the enlisted staff members expressed his personal antipathy toward one of the staff officers present. This was considered to have been a real achievement in terms of the overall process because military protocol and training is such that this is not easily discouraged but prohibited. The author considers that the difficulties manifest in this staff uncommunicativeness are bound up in what might be called a group transference neurosis which has developed. It is believed that if this can be worked through the everyday conflicts and difficulties which arise among the staff will be much less of a problem.

### SUMMARY AND CONCLUSIONS

This article reports some of the problems that repeatedly arose in the daily group meetings of a therapeutic community and the methods developed to cope with them. The community is still in a transitional stage but it is believed that other hospitals will experience similar transitions in adopting community methods of treatment.

Community methods of treatment focus on social tensions existing between patients, between staff members, and between staff and patients. The daily group meetings seen as teaching and learning situations for good social behavior have been used to create a climate in which interpersonal tensions existing within the community. In the developmental stages of creating such an atmosphere it was found necessary to deal directly with certain issues that arose frequently within the meetings. We found it necessary to require patients and staff to reveal the identity of persons involved in the discussions who had committed antisocial or antisocial acts. Because of the shortness of the length of stay for most patients the enculturation process and conscience development had to be hastened. In some instances this necessitated legal action toward an individual member for the welfare of the community. For the most part these matters were handled successfully within the group.

Passive dependent attitudes of members toward their participation in the community came up frequently. These were treated as responses to treatment and were verbalized in the meetings in such comments as the staff evaded answering their ques-

tions, that the group could not help individual members with their problems (that they required a doctor's aid), and that they had no problems.

The participation of the staff in the community still remains unsettled. Some of the staff felt insecure in the relaxation of former controls, and were only slowly able to transform to new roles in which they could feel comfortable.

---

ACKNOWLEDGMENT We are grateful to Captain Irs C Nichols MC USN for his advice and to the nurses and hospital corpsmen who participated in this program in particular to Commander Ellen Dolloff NC USN Lieutenant Commander Mary Wolfgang NC USN Lieutenant Marion Watdell NC USN and Ben Geiger Hospital Corpsman second class, USN.

## Clinicopathologic Conference

U S Air Force Hospital Sheppard Air Force Base Tex

### JAUNDICE IN INFANCY

**Summary of Clinical History** A 6-month-old white male infant was transferred here from another hospital with a history of jaundice since birth which had persisted without significant change. The urine was described by the mother as frequently darker than normal but never dark orange or brown in color. The stools were said to have been intermittently "clay colored." The patient had several episodes of vomiting and diarrhea since birth the most severe of which occurred at the age of four months when he was admitted to another hospital. Rapid improvement occurred with treatment. The patient also had had a mild non-productive cough for several months. Despite these symptoms he gained weight regularly. Several weeks before admission to this hospital it was noted that his abdomen had begun to distend.

**Physical Examination** Examination revealed a well nourished well developed white male infant with definite icterus of the skin and sclerae. The heart and lungs were normal on examination. The abdomen was slightly enlarged and the liver was palpated four fingerbreadth below the right costal margin. There was an equinovarus deformity of the right foot.

**Laboratory Studies** Initial laboratory findings were as follows:  
erythrocyte count 3 700 000/ $\mu$ l hemoglobin 10 0 grams/100 ml

From the Surg al Serv c A th time of th onf rence Col Marshall N J n en  
USAF (MC) was Commanding Off c and Ch l f th s r v c Col J n s n n  
at 2631 Lafayette Winter Park Fla

leukocyte count, 4,100/ $\mu$ l, with 84 per cent lymphocytes, 12 per cent neutrophils, 2 per cent monocytes, and 1 per cent eosinophils. Bone marrow aspiration revealed 270 nucleated red blood cells per 100 white blood cells. The reticulocyte count was 2 per cent and fragility studies were in the range of normal. Bilirubin was 7.7 mg/100 ml, with a prompt direct van den Bergh reaction. The icteric index was 40 units. Prothrombin time was 13 seconds (control, 16 seconds), and cephalin cholesterol flocculation, 2 plus in 48 hours. Urobilin could not be demonstrated in the stool. The alkaline phosphatase was 7.8 Bodinsky units. The serologic test for syphilis was negative.

**Course in Hospital.** The patient showed little change for two weeks, during which the presence of acholic stools was confirmed on two occasions. He then developed frequent paroxysms of coughing which became relatively severe and were occasionally followed by vomiting. The pharynx was moderately injected and filled with rather thick mucus. Coarse rhonchi were heard throughout the chest. Additional laboratory studies revealed a leukocyte count of 16,000/ $\mu$ l with 67 per cent lymphocytes, 6 per cent of which were reported as atypical. A culture from the throat grew *Micrococcus pyogenes* var *albus*. Roentgenograms of the chest were read as negative. The patient was treated with various antibiotics with gradual disappearance of the cough and vomiting over a three-week period. At this time a laparotomy was performed.

#### DISCUSSION

**Doctor Sullivan:** This is the case of a 6-month-old white male infant transferred here with a history of jaundice since birth. The urine was described as frequently "darker than normal" but never "a dark brown." The stools were said to have been intermittently "clay colored." The patient had several episodes of vomiting since birth, the most severe of which responded to symptomatic treatment. There was a mild and non-productive cough for several months. In spite of these symptoms the patient gained weight steadily. Several weeks prior to his admission it was noted that his abdomen had begun to distend.

Examination revealed a well-developed, well-nourished white male infant with definite icterus of the skin and scleras. Examination of the heart and lungs was within normal limits. The abdomen was slightly enlarged, and the liver was palpable four fingersbreadth below the costal margin. In an average baby the liver will be one or one and a half fingersbreadth below the costal margin. A liver four fingersbreadth below the costal margin will be down near the umbilicus. The foot deformity is not significant.

The red blood cell count was 3,700,000/ $\mu$ l with a hemoglobin of 10 grams/100 ml, which concerns many who do not deal with children.

## U S ARMED FORCES MEDICAL JOURNAL

1352

The average baby at six months of age will have a hemoglobin of around 11.2 grams/100 ml. The hemoglobin and red blood cell count in this patient do not necessarily indicate anemia, particularly as these findings are not too accurate in any laboratory and because a lot of children live on milk only. The profound anemias of childhood will be much more severe than this. In truly anemic children of six months of age a hemoglobin of 6 or 7 grams/100 ml is not uncommon.

The reticulocyte count was 2 per cent. As a normal count for this age group is about 1 per cent, this could easily be within normal limits. It does not mean much if no more than that. The fragility studies were within normal limits. The icteric index was 40 units, which corroborates the reported elevated serum bilirubin. The alkaline phosphatase was 7.8 Bodansky units, a finding within normal limits.

The child had a benign course without change for two weeks during which time the presence of acholic stools was confirmed on only two occasions. In our ward we have the nurse save the stools and we examine them ourselves. A lot of times this is much more reliable than ordering urobilinogen tests et cetera, from the laboratory. Other examinations of the stools are not reported, but only twice did the infant have really clay colored stools and this may be truly significant. He then began to have paroxysms of coughing. The larynx was moderately injected and filled with mucus. Coarse rhonchi were heard throughout the chest. The previous respiratory infections described were not particularly abnormal in frequency. The blood cell count at this time was peculiar in that there was a leukocyte count of 18,000/ $\mu$ l with a marked preponderance of lymphocytes. The infant had a pharyngitis and a bronchitis and responded to antibiotics over a three-week period. Then a laparotomy was performed.

There are in children problems more common but probably none more interesting than that of jaundice. In my pediatric practice next to upper respiratory infections I have probably seen more cases of jaundice than of anything else. The case that I usually see is that of a child two and a half to four weeks old with a physiologic jaundice a little more extreme and a little slower to clear than we are accustomed to seeing. Physiologic jaundice usually starts about the third or fourth day and the process is most extreme by the sixth to ninth day. It usually clears by the 14th day but this is not always true as I have seen it last for a little bit longer. Serum bilirubin findings during the height of physiologic jaundice have been reported as high as 20 mg/100 ml which is greatly elevated.

The next most common entity that we see is erythroblastosis fetalis, but this is an acute illness that occurs in the first few days of life. Inspissation of bile with obstructive phenomena and liver cell damage can occur but does not fit this case because the patient had no history of difficulties in the neonatal period. Sepsis can produce jaundice but is associated with the critically ill. In the absence of good therapy such children do not live long—certainly not six months.

Congenital syphilis produces profound anemia in acutely ill children, multiple areas of periostitis and all the other symptoms of congenital syphilis that have not been described in this child.

There are certain infections that involve the liver in the newborn period and infancy that might fit the picture we have described here. In the past two years there have been numerous reports of homologous serum jaundice being transmitted from the mother to the child. It is surmised that this is one of the causes of congenital abnormalities of the extrabiliary and intrabiliary duct system.

The viruses that cause herpes simplex in adults and herpes stomatitis in children may also produce transplacental infections. The parents reported have had a rapid fulminating hepatitis which shortly terminated in death. To my knowledge cases with a long course simulating an obstructive jaundice have not been reported.

Another disease in infants that we have become acquainted with in the last few years is infectious mononucleosis presenting only jaundice, hepatomegaly and splenomegaly. This picture could well fit this child. The only really remarkable abnormality in the blood cell count is the marked preponderance of lymphocytes which again we see occasionally in infection in children. A heterophile antibody test was not reported in this case. The congenital biliary obstructions are the diseases most likely to be found in this age group. At times they are quite confusing. These children grow and do well but they have stentorhea with increasing jaundice and their stools are clay-colored more or less constantly. This child was here some six weeks and the stools were noted to be clay colored on only two occasions. Probably a diagnosis of absence or complete atresia of the hepatic ducts with complete obstruction is not justified. The picture is perfectly compatible with congenitally small bile ducts with intermittent or insufficient biliary drainage. The inspissation of bile causing temporary plugging has been discussed at great length, and there have been a few such cases reported. I have had the privilege of seeing and following one such case.

Fibrocystic disease can occasionally involve the liver, primarily in association with repeated upper respiratory infections. If this were true in this case you would certainly anticipate stentorhea, more diarrhea than is described and a malnourished child who is not doing well. It would be most unusual for fibrocystic disease to derange hepatic function to the degree present in this patient without more evidence of lung and pancreatic involvement.

For my diagnosis, then, I would list first some congenital abnormality causing temporary or intermittent obstruction of the bile ducts. Infectious mononucleosis is my second choice, and hepatitis due to homologous serum jaundice is my third.

Doctor Chamberlain I think that Doctor Sullivan has covered the differential diagnosis and clinical aspects of the various forms of jaundice in the newborn infant quite well I think that we are forced to conclude that this is an obstructive type of jaundice simply because the clinical picture does not fit a hemolytic type of jaundice and the hepatitis although possible does not seem to be quite as likely as the obstructive type By and large the majority of the obstructive types of jaundice in infancy are caused by atresias of the biliary tract which can take multiple forms If the intrahepatic passages and the upper portion of the hepatic ducts and the common bile duct are patent the case is potentially curable by surgical means It is not possible and certainly not practical to differentiate at all times the exact type of obstructive jaundice present Once the diagnosis of obstructive jaundice is made an exploratory laparotomy is obligatory to find exactly what is going on and whether or not the patient can be cured If the passages in the liver and the upper portion of the common bile duct are patent the common bile duct or sometimes the gallbladder can be anastomosed to the duodenum If the atresia takes place within the liver of course it cannot be corrected surgically In this event the incision is closed after removal of a biopsy specimen of the liver and exploration of the bile duct By and large a stricture high up in the hepatic ducts even though extrahepatic is difficult to treat surgically

The other causes of obstructive jaundice in the newborn infant have been mentioned Inspissated bile frequently seems to be associated with obstruction of a small bile duct although we cannot actually call these atresias It is probable that if the bile ducts were not small the bile would not become inspissated.

Erythroblastosis fetalis is more frequently associated with inspissated bile than any other single disease and the reason for this is the excess bile pigment and debris I think that erythroblastosis with inspissated bile producing this degree of jaundice is unlikely here for reasons that have been mentioned—the patient should have had a profound anemia and a little different clinical course

Large lymph nodes pressing on the bile duct can cause jaundice which is typically intermittent and thus could be due to any disease that causes lymphadenopathy Any neoplasm in the neighborhood of the bile duct can cause obstructive jaundice but in infancy such lesions are quite rare

A cephalin-cholesterol flocculation of 2 plus and hepatomegaly are consistent with obstructive jaundice of six months duration because there is usually a fair amount of secondary biliary cirrhosis in these patients The evidence of intermittent jaundice bilirubin of 7.7 mg/100 ml and icteric index of 40 units are slightly

against biliary atresia because most patients with atresia lasting for six months have more intensive jaundice than this.

In this hospital the patient was noted to have acholic stools on two occasions. I do not know from the protocol whether that means that the stools were only examined two times or whether they were examined at other times and were not found to be acholic.

Doctor Jensen: There is nothing in the chart to indicate that there was ever bile in the stool.

Doctor Chamberlain: Apparently the jaundice did not vary in intensity but sometimes this can be misleading. It is difficult for parents to be able to estimate the degree of jaundice especially if the jaundice should increase slowly. I think the biggest point against an inspissated bile syndrome is that after six months the patient still had about the same amount of jaundice as he had at the beginning. I believe we all agree that laparotomy was indicated in this case.

*For a diagnosis I would have to say that biliary atresia was my first choice and inspissated bile syndrome a close runner up.*

Doctor Warner: Not very much has been said about the possibility that the jaundice was caused by a pigment calculus for this child may have had hemolytic anemia. If that were the case we have ample evidence that there was an obstructive jaundice even though it may have been intermittent. I do not see that the peculiar hematologic findings have been satisfactorily explained. There is, on one hand the relative lymphocytosis and on the other evidence in the bone marrow of increased erythropoietic activity in association with a relatively normal reticulocyte count. The absence of a palpable spleen would be unusual with hemolytic anemia or with such prolonged obstructive jaundice. This patient had actually had obstructive jaundice for six months and so I would expect that whatever the cause there would at least have been a slight degree of biliary cirrhosis. The protocol mentions a swelling of the abdomen for several weeks just prior to admission and perhaps this was the beginning of ascites. At any rate I think that the possibility of hemolytic anemia with a bile pigment stone has to be considered and that certainly, whatever the cause of the obstructive jaundice early biliary cirrhosis was also present.

Doctor Jensen: We might mention one other possible diagnosis in this discussion that is the so called cyst of the choledochus. This patient however is a little young to have this lesion. The word cyst is a misnomer because these lesions are due to an enlargement of the common duct similar to megaloureter or possibly Hirschsprung's disease. Jaundice usually occurs later than in this patient. The discussion of this case, I think, depends to some extent on the accuracy of the history. Whether or not the jaundice actually fluctuated or

the stools contained bile during this time is most important but it is almost impossible to determine these events from the history as given. The history concerning the pregnancy and delivery was apparently non-contributory. Doctor Wilson do you have any comment regarding the blood picture?

Doctor Wilson The values as reported are rather unusual. The child seemed to be anemic as the hemoglobin was 10 grams/100 ml and the red blood cell count 3 700 000/ $\mu$ l. The white blood cell count of 4 400/ $\mu$ l was certainly low for a child of his age and 84 per cent lymphocytes was abnormal. The differential count in a child of this age usually includes about 60 per cent lymphocytes. The bone marrow aspiration was rather vaguely reported it being stated that there were 270 nucleated red blood cells but it was not stated whether these were normal maturation of the red blood cells. We do not know whether these were primarily normoblasts whether they were erythroblasts or if any megaloblasts were present. A ratio of 270 nucleated red blood cells per 100 white blood cells is rather high unless there has been a depression of the white cell series. Usually there are around 400 white blood cells per 100 nucleated red blood cells. This finding and the anemia would definitely be consistent with marked hemolysis however a reticulocyte count of 2 per cent is not consistent. Fragility studies were in the range of normal. I assume that this was saline fragility. We have been given no description of the red blood cells in the peripheral blood. It certainly would appear that some hemolytic process was going on or that marked depression of the myeloid element of the bone marrow was present.

Dr Sullivan's diagnosis  
Congenital abnormality of the bile ducts, or infectious mononucleosis or hepatitis due to homologous serum jaundice

Dr Chamberlain's diagnosis  
Biliary atresia or inspissated bile syndrome

Doctor Morsh At laparotomy this child was proved to have a complete obstruction of the hepatic duct just proximal to where the cystic duct joins the hepatic duct to form the common bile duct. The hepatic duct proximal to the obstruction was dilated approximately 3 cm and distended with bile. The gallbladder was present and appeared to be normal. A side-to-side anastomosis between the hepatic duct and the jejunum was done. Postoperatively the child did well for about four days and bile reappeared in the stool. On the fourth postoperative day the child became lethargic and developed a fever up to 104 F. He became comatose and died on the following day.

Capt William L. Wilson USAF (MC) then Chief Medical Officer  
Capt Robert L. Morsh USAF (MC) then Chief Laboratory Sergeant

## PATHOLOGIC FINDINGS

The autopsy was restricted to the abdomen through the surgical incision. Examination of the liver, duodenum, and stomach showed that the anastomosis was functioning and that there was bile both in the stomach and in the duodenum. The grossly nodular, bile stained liver weighed approximately 500 grams and the cut sections showed dilation of the biliary system within the liver and marked portal fibrosis.

## Pathologic diagnoses

- 1 Cirrhosis, secondary to congenital stenosis of the common hepatic duct
  - 2 Centrilobular bile stasis
  - 3 Functioning choledochojejunostomy
- 

PRIMARY MILIARY TUBERCULOSIS  
OF THE LIVER

"Primary miliary tuberculosis of the liver was found in 12 cases under conditions showing that it is not rare but is easily overlooked as a possible cause of obscure illness. The symptoms found in all these case histories included fever, lassitude, weakness, anorexia, weight loss, chills, and drenching sweats. Reaction to the Mantoux test was positive in all. No cases of jaundice were seen. Hepatomegaly, splenomegaly, ascites, alcoholism, and exposure to tuberculosis are clues to the diagnosis. Needle biopsy of the liver is valuable but need not be done immediately in very weak patients, since recognizable tubercles remain in the liver for weeks after successful therapy has started. Isoniazid and aminosalicylic acid are now given to every patient with streptomycin and steroids if necessary. The response in the cases here described was remarkably good and sometimes dramatic. All of the eight patients whose treatment was considered adequate recovered without sequelae."

## SERVICE ARTICLES

# APPLICATION OF PSYCHODYNAMIC PRINCIPLES TO PSYCHOTHERAPY IN MILITARY SERVICE

HARRY TROMMAN, Lieutenant, MC USAF  
I HYMAN WEILAND, Lieutenant Colonel, MC USAF

**N**OTWITHSTANDING the recent emphasis on pharmacologic agents, psychotherapy remains the most important and essential tool for the psychiatrist. All forms of psychotherapy during the past half century have been markedly influenced by psychoanalytic principles. Even when the orthodox psychoanalytic approach is not indicated as in the military service, psychodynamic treatment techniques can still play a vital role.

There are characteristics of the military services that prohibit a thoroughgoing psychoanalytic approach and it is unnecessary for the psychiatrist to rigidly model his treatment techniques on those of the psychoanalyst. The type of case under consideration, the intensity of the psychotherapeutic endeavor, the time available, and the degree of improvement considered adequate necessitate a more flexible approach on the part of the psychiatrist and a greater utilization of those aspects of the military situation that can be helpful to the patient.

### THE MILITARY SITUATION

Certain characteristics of the military situation actually may create difficulties for the psychiatrist, especially if he cannot consider them as social realities. It is necessary to recognize the reality of these characteristics and appreciate that adequate psychotherapy can be done within the limits they impose.

By its very nature the totality of the military is somewhat inflexible, since the service must function as a highly integrated activity with purposes somewhat at variance with the alleviation of problems of neurotically vulnerable individuals. For this reason the adherence to regulations and a tightly knit disciplinary organization, though at times frustrating for the psychoanalytically oriented psychotherapist, are realistically appropriate.

---

For the Naval Medical Staff, Dr. Harry Tromman is the Department of Psychiatry, University of Chicago. Dr. I. Hyman Weiland is the Commander, The Eisenhower Institute, Philadelphia, Pa.

Although psychotherapists have found that their work proceeds most effectively when the therapeutic relationship is colored by a permissive atmosphere, this is offset by the necessity for obedience that is present in the total military situation. Insofar as the psychiatrist must also function in an administrative capacity, the treatment he gives is often handicapped by this secondary role. On the one hand, with regard to those patients who have motivational problems regarding their adjustment to the service, he must make dispositional decisions regarding separation of patients from the service, on the other hand, he must treat patients who frequently distort his function as administrator or physician. Thus, the psychiatrist undergoes a certain confusion regarding which function is primary. Frequently, a poorly motivated patient will exploit the psychiatrist's double function in order to resist psychiatric treatment, and will orient himself primarily in terms of a discharge from the service.

Certain more selective aspects of military life may increase the psychiatrist's difficulty in treatment. His time is often limited, and he or his patients are subject to practical necessities of military life that may interfere with the duration of treatment or its regular performance. The psychiatrist or his patients frequently are transient, so that neither may have the secure knowledge that treatment can proceed over a prolonged period of time without interference.

These considerations often may affect the psychiatrist in an adverse manner when he considers the possibility of performing adequate psychotherapy. He may not consider the positive aspects of military life that serve as a stimulant toward improvement in the patient and can be utilized by the psychiatrist advantageously during the course of treatment.

#### ADVANTAGES OF THE MILITARY SERVICE FOR THE PSYCHOANALYTICALLY ORIENTED THERAPIST

Of great importance to the psychiatric patient is the opportunity afforded to participate in a markedly cohesive group. He frequently has an opportunity for identifying himself with values and activities that are concrete, well formalized, and ego supportive. The group is conducive to dependency gratification and is characterized by a mutual appreciation for common problems. For the patient who has difficulty in the area of ego control, the group provides a clear cut understanding of what is positively and negatively sanctioned. It frequently is observed that the group can tolerate a psychologic disturbance in one of its members in a most understanding manner. There is little social stigmatization with such a disability, and there is a sympathetic awareness that men may react with neurotic symptomatology under stress. The group provides an opportunity for the temperate

alleviation of many of the stresses associated with individual responsibility

During the course of psychotherapy, it often is necessary for the patient to reexperience feelings and emotions that were characteristic of his relationships with his parents in early childhood. The reestablishment of these parental relationships is often facilitated simply by the hierarchical structure of the military situation. It is more possible for the patient to transfer some of these childhood emotions toward figures who, because of their rank, have already attained for him a role of father or brother surrogate.

Generally, the psychiatrist prefers to interfere as little as possible with the realities in a patient's life. Occasionally, however, one does meet the patient for whom it is desirable to effect some environmental manipulation. The presence of organization, the readiness with which this organization lends itself to pliability, and the assurance of proper liaison between line and medical officers, can be utilized therapeutically. For the patient who has difficulty in controlling acting out and aggressive outbursts, the presence of well-defined limits as to what is appropriate and will be tolerated serves as a stimulant to the development of internal control, so that in time he can mature sufficiently to decide for himself when an antisocial and unacceptable impulse must be regulated.

A constant hazard in civilian psychotherapy is the danger that the patient will relate to the psychiatrist in a destructive dependent, nontherapeutic, clinging relationship. In the military service, the emphasis on rapid improvement and the lack of opportunity for time-consuming therapeutic relationships often obviate the development of this difficulty. Every civilian psychotherapist has had experience at some time in his career with difficulties in treatment when relatives have frequent access to the psychotherapist and influence the patient in some manner that will increase his resistance to continuing the treatment. Frequently, the geographic distance from home and the sharp differentiation between civilian and military life free the patient and the psychiatrist from this additional burden.

#### PSYCHODYNAMIC PRINCIPLES

By and large, orthodox psychoanalytic treatment techniques cannot be utilized in the service. These techniques are time-consuming, expensive, and frequently not indicated in terms of the patient's disability. Psychoanalysis is a model procedure that represents an end point along a continuum on which similar, but attenuated, techniques can be utilized. In the military service it is possible to use these attenuated techniques in such a manner as to derive the most benefit in achieving psychotherapeutic aims.

In a therapeutic setting, it has proved to be most helpful to divorce the administrative and the therapeutic functions of the psychiatrist. The patient is handled administratively by his ward medical officer, and treatment is carried out in regular interview sessions with the psychiatrist, who is not involved in such matters as granting liberty, deciding on a final disposition of the patient, and instituting disciplinary action when indicated. The following case will serve as an illustration.

**Case 1.** A 22 year old sergeant with 3 years of active duty was admitted to the hospital because of an anxiety reaction that had been present for about a year. At the time of admission the patient was convinced that his symptoms were the result of stresses to which he had been exposed while on active duty. His initial motivation was to be separated from the service. Following his admission work up, he was assigned to a psychiatrist who was not his ward medical officer and was told that this psychiatrist would treat him but would take no responsibility for the final disposition regarding his returning to duty or separation from the service. Initially the patient attempted to manipulate the psychiatrist into a more active role and tried to resist treatment by bringing up dispositional matters. The patient was advised to discuss these with his ward medical officer. After the patient began to face his problems, his symptoms improved. At the end of a three-month period of hospitalization and treatment, he was interviewed by his ward medical officer who recommended that he be returned to full duty.

In the service, the need for establishment of a sense of direction and a sense of identity can be facilitated by meaningful situations and thus exploiting to best advantage the patient's capabilities, as case 2 illustrates.

**Case 2.** A 19-year old private, first class with 1½ years of active duty was admitted to the hospital complaining of masochistic tendencies and depressive feelings of several years duration. Prior to admission to the service, the patient had been active in high school sports where he satisfied certain exhibitionistic tendencies and leadership needs by taking part in dramas and athletics. After a short period of hospitalization, it was determined that he had difficulties considering himself to be a part of the group. He could doubtless function in a better capacity and overcome his symptoms if his leadership capacities were more fully utilized. The liaison officer suggested transferring the patient to the military police. This was done and he "found himself" responding very well to his new assignment. His aggressive impulses were utilized in socially acceptable channels and he no longer had to turn them in a reflexive masochistic fashion.

It has been desirable, after a sufficient period of psychotherapy and hospitalization, to recommend that the patient be returned to limited duty status, treatment being continued during the period of limited duty. This avenue of approach can be utilized for three

patients who require a period of "weaning" toward the end of treatment rather than abrupt termination. Case 3 is an example.

**Case 3.** A 47-year-old lieutenant developed a neurotic depressive reaction following a divorce three years prior to admission to the hospital. Initially, the patient related himself to the therapist in a markedly dependent regressive manner. As he was encouraged in this dependent relationship, the patient overcame feelings of depression and a limited duty assignment was recommended. During the course of the patient's return to limited duty, his progress was followed in weekly interviews, and he managed to attain a more independent and self-assertive status without again becoming depressed.

In psychodynamic therapy, it frequently is possible to effect a major personality change in a patient without producing insight, if the relationship with the therapist is sufficiently corrective and emotionally meaningful. This can be done with the patient for whom the heightened authoritarian aspect of the doctor-patient relationship recapitulates his relationship with his father, so that the patient reacts to the therapist in a manner that closely resembles his early childhood reaction. In such a situation, the therapist must then assume a role which reveals to the patient his neurotic reactions and their inappropriateness.

**Case 4.** A 27-year-old lieutenant (junior grade) with 2½ years service was admitted to the hospital with an acute anxiety reaction. Though a capable and efficient officer aboard his ship, the patient frequently felt the need of a strong authoritarian figure upon whom he could depend. His admission was precipitated by the departure of a friend several years older, whom the patient had frequently consulted for advice and support. During the initial phase of treatment, the patient utilized the difference in military rank to permit himself to relate to the therapist much like a helpless child. The therapist, however, made few comments to the patient, asked few questions, and gave no advice. The patient became increasingly disturbed by this behavior of the therapist until it was pointed out to him that he had sufficient maturity not to need this kind of support. In time, the patient saw how this characteristic had determined so many past relationships and began to experiment at being more self-assertive and aggressive. These endeavors were encouraged by the therapist, and the patient soon overcame his more dependent anxiety provoking feelings.

#### SUMMARY

Psychotherapy as a treatment procedure is of great importance to the military psychiatrist. The military service provides several advantages for the psychoanalytically oriented psychiatrist that are of aid to him in doing efficient and useful psychotherapy. It is the application of modified, flexible psychodynamic techniques in the realistic social setting of the military service that produces significant results in treatment.

# DENTAL INCIDENT RATE IN PARACHUTING

ROBERT I. SIEBER, Lieutenant Colonel DC USAF

ROBERT P. MOSS Major DC USA

**D**OES parachuting cause a proportionately greater number of dental accidents than any other type of military or non-military activity? Should a man who wears a removable prosthetic appliance, either full or partial, remove it from his mouth while engaging in parachute activities, or retain it in place? Over the past 15 years, these two questions have arisen in connection with parachute activities and dental needs. To our knowledge, no specific studies of these questions have been made and no definite conclusions have been reached. All reports up to this time have been based on isolated experiences and pure speculation.

## PROCEDURE

A record sheet was prepared (fig. 1) and distributed to the three dental clinics servicing airborne troops at this station. Examining personnel were instructed in its use and requested to complete a form for each patient who reported to the clinic with a complaint of dental injury or denture loss sustained during airborne training or actual parachuting. Any peculiar or unusual circumstances related to the event were to be described. The survey was carried on for a period of 18 months in order to obtain adequate coverage and significant data.

## RESULTS

During the survey period, 178,672 parachute jumps were performed and 10,069 airborne trainees were graduated from the basic airborne course. In these months not one case of "high altitude pain" was reported, but the injuries and dental losses shown in table 1 occurred while performing parachute jumps. During basic airborne ground training, there were two instances of partial dentures being broken.

## COMPARISON

A total of 48 fractures (either maxillary or mandibular) were treated at this station during the period covered. Only one of

---

From Division Area Dental Clinic and Office of the Dental Surgeon, 82d Airborne Division, Fort Bragg, N. C. Maj. Moss is now at Army Medical Service School, Brooke Army Medical Center, Fort Sam Houston, Tex.

In an effort to determine the frequency extent and type of dental accidents arising from airborne activities your cooperation is requested in filling out the following on all airborne personnel presenting themselves for dental treatment following such accidents or injuries

Figure 1

these was a direct result of parachuting. The remainder were caused by blows, falls, automobile accidents, et cetera, all having no relation to parachute activities.

During this same period 1,415 broken dentures were repaired at this station. Only five of these were broken as a result of parachuting or ground training for parachuting.

No comparison figures are available for the total number of lost dentures, fractured natural teeth or soft tissue injuries from all causes during the survey period, but we believe that

in these items also, parachuting contributed only a minor percentage of the total

1 due to biting tongue 2 due to equipment webbing which forced soft tissue against teeth

### CONCLUSIONS

Aerodontia is not a primary factor in dental service for air borne personnel

The rate and extent of dental injuries and oral embarrassment due to parachute duty is extremely slight and of no particular significance in relation to the nature of the hazardous duty performed, and there does not appear to be any correlation between an individual's experience (number of jumps previously completed) and his susceptibility to a dental accident. The fact that all three of the cases of fractured natural teeth occurred after the sixth jump of the individuals concerned is probably coincidental.

The dental accident rate was approximately 0.01 percent of the completed jumps. Inasmuch as about 8 percent of the air borne troops at this station have some type of prosthetic appliance, it is recommended that these appliances be retained in place, if only to aid in supporting the soft and hard dental structures.

Based on this study, no special consideration appears to be warranted from the dental standpoint for personnel on airborne status other than routine dental care.

## CASE REPORTS

### Decompression Sickness at Medium Altitude

STUART A SCHNECK *Captain USAF (MC)*

**W**HILE all flight surgeons are familiar with decompression sickness or dysbarism many military physicians in other specialties or in general medicine are unaware of the symptoms and signs of this condition. Moreover few of these physicians realize the inherent seriousness of a pathologic situation in which the patient initially may present rather mild symptoms followed by collapse or death.<sup>1</sup> This report concerns the occurrence of a moderately severe case of dysbarism with central nervous system involvement first attended by a physician who was not a flight surgeon. This situation could occur to any medical officer particularly at an Air Force base and demands more than casual handling.<sup>1</sup>

#### CASE REPORT

The patient aged 30 a test pilot for a maintenance squadron at a flying training Air Force base with over 900 hours of jet aircraft flying time had no previous history of any manifestations of dysbarism. The night before the flight to be described he had four drinks of bourbon whisky the last one approximately 13 hours prior to the development of his symptoms. He had 5½ hours of sleep and an adequate breakfast before the flight. No symptoms of fatigue or physical stress were noted prior to flying.

On 25 November 1956 the patient departed Portland Municipal Airport Portland Oreg. at 1330 hours in a T 33 aircraft with destination Lowry Air Force Base Colo. He occupied the rear seat inasmuch as he was receiving an instrument check from another pilot in the front seat. There was no period of preoxygenation. On takeoff and up to 5 000 feet 100 per cent oxygen was breathed and at 5 000 feet the regulator was switched to the "normal" oxygen setting (This setting gives a mixture of oxygen and ambient air in which the per cent of oxygen increases as one ascends up to an altitude of 34 000 feet at which time 100 per cent oxygen is being breathed.) About 45 minutes after takeoff the aircraft reached cruise altitude of 40 000 feet with a cabin altitude of 24 400 feet and approximately 15 minutes later (1

hour after takeoff) he noted difficulty in focusing his eyes on the instrument panel. He immediately turned his oxygen regulator to 100 percent oxygen, held his mask tighter against his face and asked the pilot in the front seat to check the cabin altimeter. The pilot stated it was still 24,400 feet.

After approximately 5 minutes on 100 percent oxygen with no noticeable improvement in his vision, the patient turned his oxygen regulator to the pressure setting 1341 (This setting usually delivers oxygen under a pressure equal to 8 inches of water.) Shortly afterward his vision did improve slightly but was not perfect. He noted difficulty in reading the full aircraft serial number which is a series of six numbers located on the instrument panel. At first he could read only one number at a time and could not even see the others. After about 15 minutes on pressure oxygen his vision improved to the extent that he could see four numbers at once. He checked this with his left and right eyes separately and then together and found that his vision was still the same.

Approximately 15 minutes after his initial symptoms, the patient very suddenly experienced a sharp pain in his left knee. Soon afterward he noted a slight pain in his right knee and spots on both thighs that "half itched and half hurt." Ten minutes later he noted the rapid development of a very severe headache over his entire head but primarily located behind his left eye. At this time he went back to 100 percent oxygen without pressure because of the discomfort of pressure breathing and the fact that there was no improvement in his condition. During the course of 35 minutes of pressure breathing his throat had become very dry and a slight cough had developed.

Descent was begun approximately 1 hour after the original visual symptoms appeared and after passing through 20,000 feet actual altitude his knee pains and itching disappeared. The patient estimates the total time at 40,000 feet actual altitude (24,400 feet cabin altitude) was 75 to 80 minutes and that he was above 30,000 feet for an additional 20 minutes.

After landing the patient reported "After departing the aircraft [1½ hours after the onset of the symptoms] I noticed that I did not have complete control of my muscles. They were slightly jerky and twitchy. I could not walk straight and was slightly dizzy. My vision was somewhat blurred. I could not speak words clearly and my voice tended to high pitch. My thinking did not seem clear and I had some difficulty in understanding words. [He later added that the other pilot frequently had to repeat statements before he could understand them.] I sat down in Base Operations for approximately 20 minutes. The only symptoms that had disappeared were the knee pains, the itching and the cough. All others were gradually getting worse. The headache grew to an almost unbearable state. I requested transportation to the hos-

pital and arrived there approximately 40 minutes after landing. I was in a deep state of depression and had a tremendous urge to cry but had no logical reason to do so.

The medical officer who first saw this patient was an orthopedic surgeon whose first impression was that he was dealing with a sinus headache or migraine. The insistence of the patient that he wanted to see the flight surgeon because he knew this was not a sinus headache made the medical officer consider dysbarism despite the fact that this was a syndrome with which he was not too familiar. He did remember a discussion of the treatment of this syndrome at a hospital staff meeting and placed the patient at rest on 8 liters of oxygen per minute for 15 minutes. A flight surgeon was called and he examined the patient at 1900 hours. An hour later a second flight surgeon examined the patient.

His blood pressure was 110/70 mm Hg, pulse 70 per minute and regular, temperature 97.4°F, respiration 16 per min, weight 140 pounds and height 5 feet 5 inches. The fundi were normal. There was no nystagmus, pupillary reflexes and extraocular movements were normal. A gross confrontation test revealed intact visual fields and the patient's vision subjectively was no longer blurred. The neurologic examination revealed only slight weakness of the right hand. The Romberg test was negative. General physical examination findings were normal. The patient stated that he still did not feel quite right and still had a sensation of staggering when walking. He was definitely unsteady when his walking was observed.

The patient had received a total of 8 Cafertog (brand of ergotamine with caffeine) tablets in a 1 hour period before the first flight surgeon saw him. He had been nauseated before admission and at 2200 hours he vomited once. Definite improvement was then noted in his symptoms. The headache began to subside about 4 hours after admission. He was given 100 mg of Nembutal (brand of pentobarbital sodium) and slept fitfully during the night. Vital signs remained normal.

In the morning the patient had only a slight headache and a subjective feeling of general weakness. Weakness of the right hand was no longer apparent and no staggering on walking was noted or felt. Vision was 20/20 bilaterally for near and distant and depth perception, accommodation, phorias and point of convergence were all normal. Recheck of his fundi was negative. Pupillary reflexes, tangent screen and perimetry were normal as were the general physical and neurologic examination findings. Test for carbon monoxide drawn on admission was negative. Laboratory studies performed the night of admission revealed a negative urinalysis. The hemoglobin was 15.7 grams per 100 ml. The white blood cell count was 8,400 per  $\mu$ l with 56 per cent neutrophils, 40 per cent lymphocytes, 1 per cent eosinophils and 5 per cent basophils. The hematocrit was 43 per 100 ml and the sedimentation

rate was 3 mm per hour. A roentgenogram of the chest was normal. The patient stated that a vague headache and a feeling of giddiness persisted all day.

On 27 November the patient's headache was gone and he felt fine. Electroencephalographic findings were reported as normal. A neurologic examination revealed no abnormalities. On 29 November the patient again felt fine and he was released to full flying duty. He has since flown in the same aircraft to altitudes of 40,000 feet without any difficulties.

Final diagnosis was decompression sickness manifested by central nervous system involvement "bends" and parosmia.

### COMMENT

There are many reports in the literature of cases of disbarism occurring above 30,000 feet.<sup>1,2,3,4</sup> The lowest previously recorded case of decompression sickness with central nervous system involvement occurred in 1914.<sup>5</sup> The individual concerned had been at 26,000 feet cabin altitude for 1 hour and 10 minutes, and then the aircraft climbed in about 4 minutes to a cabin altitude of 29,000 feet. He collapsed and died 5 hours and 21 minutes after the onset of symptoms.

Downey in discussing this case mentioned another occurring at a cabin altitude of 26,000 feet,<sup>6</sup> and in a personal communication referred to an unreported case occurring at 29,000 feet in 1953. Sproull<sup>7</sup> reported a fatal case of decompression sickness in the Royal Air Force which occurred 19 hours after a 1 hour flight between 25,000 and 30,000 feet.

While decompression sickness with central nervous system involvement is unusual below 30,000 feet, bends, which is another manifestation of decompression sickness, has been known for a long time to occur below this altitude. There is a recent report of bends affecting an officer in a B-52 aircraft at a cabin altitude of only 23,000 feet.<sup>8</sup> Strenuous exercise can induce bends at altitudes as low as 22,000 feet.<sup>9</sup> It appears, however, that this may be the first case of disbarism with central nervous system involvement reported to have occurred below 26,000 feet.

To verify the reported cabin altitude of 24,400 feet the pilot in the front seat, who was totally free of symptoms during the flight, was questioned. He reported that he checked the cabin altimeter several times during the flight and was positive that it never exceeded 25,000 feet. The cabin altimeter was placed in a vacuum chamber and checked with a mercury barometer. At 10,000 feet the altimeter was 100 feet in error and there was no other error in the instrument between sea level and 45,000 feet.

The aircraft concerned was flown at 40 000 feet actual altitude for 30 minutes and at no time did the cabin altimeter exceed 25 000 feet The lowest cabin altitude noted at 40 000 feet was 24 500 feet The aircraft's oxygen and pressurization systems were checked and no discrepancies were found The patient's mask and connections were checked by the physiological training unit at the time of his admission to the hospital and nothing amiss was found The aircraft had 450 p s i (pounds per square inch) of oxygen on takeoff and on landing 225 p s i remained The patient who is unusually familiar with his own hypoxia symptoms checked his mask, oxygen pressure and blinker many times during the flight and throughout most of the flight held his mask firmly to his face He did this despite the fact that he always wears a very tight fitting mask

From these checks and from the progressive pattern of the patient's symptoms after he was on the ground it seems certain that hypoxia is ruled out The headache dysarthria staggering weakness of the right hand visual impairment, and difficulty in comprehension are certainly suggestive of multiple intracranial lesions presumably gas bubbles fat emboli or vasospasm While no lumbar puncture was done there were no signs indicative of meningeal irritation or papilledema to warrant consideration of intracranial hemorrhage The onset course, and recovery pattern are all consistent with the diagnosis of dysbarism

### SUMMARY

The need for a knowledge of decompression sickness on the part of military physicians has been emphasized A case of dysbarism occurring at a cabin altitude of 24 400 feet has been presented This is believed to be the lowest reported altitude for such an occurrence

## A MESSAGE FROM THE A M A

The Message last month dealt with the revision of the Principles of Medical Ethics acted upon at the 106th Annual Meeting of the American Medical Association in New York City in June 1957. Among the wide variety of other subjects acted upon by the House of Delegates were the Federal Government's Medicare Program, new standards for medical schools, a new statement on occupational health programs, and the issue of Social Security benefits for physicians.

The House considered three resolutions dealing with the Federal Government's Medicare Program for the dependents of servicemen. The delegates adopted one resolution condemning any payments under the Medicare Program "to or on behalf of any resident fellow, intern or other house officer in similar status who is participating in a training program." Government sanction of such payments, the House declared, would give impetus to the improper corporate practice of medicine by hospitals or other non-medical bodies. Such proposals, the House added, would violate traditional patterns of American medical practices, seriously aggravate problems of hospital-physician relationships, encourage charges by hospitals for residents' services to patients not under the Medicare Program, and create a variety of additional problems in such areas as medical licensure and health insurance.

In another action on Medicare, the House recommended that the decision on the type of contract and whether or not a fee schedule will be included in future contract negotiations should be left to individual state determination. In this connection, however, the House restated the A M A contention that The Dependents' Medical Care Act as enacted by Congress does not require fixed fee schedules, the establishment of such schedules would be more expensive than permitting physicians to charge their normal fees, and fixed fee schedules would ultimately disrupt the economics of medical practice. The House also suggested that the A M A attempt to have existing Medicare regulations amended to incorporate the Association's policy that the practice of anesthesiology, pathology, radiology, and physical medicine constitute the practice of medicine, and that for services by physicians in these specialties should be paid to the physicians rendering the services.

To replace the "Essentials of an Acceptable Medical School," initially approved by the House of Delegates in 1910 and most recently revised in 1951, the House adopted a new statement entitled "Function and Structure of a Modern Medical School." Presentation of the document followed a year of careful study by the Council on Medical Education and Hospitals in collaboration with the Association of American Medical Colleges.

The statement is intended to provide flexible guards which will "assist in attaining medical education of even higher standards" and "serve as general but not specific, criteria in the medical school accreditation program." The document encourages soundly conceived experimentation in medical education and it discourages excessive concern with standardization.

"No rigid curriculum can be prescribed for accomplishing the objectives of medical education," it states. "On the contrary, it is the responsibility of the faculty of each school continually to re-evaluate its curriculum and to provide in accordance with its own particular setting and in recognition of advances in science a sound and well integrated educational program."

The House also approved a new statement on the "Scope, Objectives, and Functions of Occupational Health Programs" submitted to the Board of Trustees by the Council on Industrial Health. The Board report to the House said "The statement describes and defines orthodox implant medical programs as understood in this country today and distinguishes clearly between such programs and the various plans for comprehensive medical care of the sick. It should help to resolve misunderstandings concerning the specialties of occupational medicine."

In adopting the statement, the House agreed with a Reference Committee report which declared that "The House has reported a statement which for the first time clearly defines the scope, objectives, and functions of occupational health programs. It marks the needs and boundaries of occupational health programs in the practice of medicine and it clearly charts the pathways of communication between physicians in occupational health programs and physicians in the private practice of medicine."

Two resolutions favoring compulsory inclusion of physicians in the Federal Social Security System and another one calling for a nationwide referendum of A. M. A. members on the issue were rejected by the House. The delegates reaffirmed their opposition to compulsory coverage of physicians under the Old Age and Survivors Insurance provisions of the Social Security Act. They also recommended a strongly stepped up informational program of education which will reach every member of the Association explaining the reasons underlying the position of the House of Delegates on this issue.

The House, at the same time, reaffirmed its support of the Jenkins Keogh bill. These bills, which are now pending before the House Ways and Means Committee, would, if enacted, permit self-employed persons, including physicians, to defer tax payments on amounts used to purchase private retirement annuities.

---

## DEATHS

114 Donald Lieutenant MC USN of Spring House Pa. stationed at the U S Naval Retraining Command Portsmouth N H graduated in 1954 from the University of Pennsylvania School of Medicine Philadelphia Pa. appointed a Lieutenant in the United States Naval Reserve 12 October 1956 ordered to active duty 4 October 1956 died 24 June 1957 age 28 at Exeter Hospital Exeter N H of believed acute pancreatitis

LARRABEE Wayne Fox Captain DC USA of Norfolk Nebr. stationed at the Dental Detachment U S Army Cartison Fort Bragg N C graduated in 1952 from the University of Nebraska College of Dentistry Lincoln Nebr. entered enlisted service in the Army of the United States 29 January 1943 commissioned First Lieutenant in the Medical Administrative Service 19 September 1943 while on active duty commissioned a First Lieutenant in the Dental Corps of the U S Army Reserve and ordered to active duty 16 November 1953 commissioned a First Lieutenant in the Regular Army 7 March 1955 died 19 May 1957 age 34 near South Hill Va. the result of an automobile accident

ROTH Barbara Ann Second Lieutenant ANC USAR of Cincinnati Ohio stationed at U S Army Hospital Fort Ord Calif. graduated in 1955 from the Deaconess Hospital School of Nursing Cincinnati Ohio appointed a Second Lieutenant in the United States Army Reserve 13 July 1956 ordered to active duty 10 August 1956 died 13 May 1957 age 22 at the U S Army Hospital Fort Ord of lymphatism and pneumonia

## MILITARY MEDICO DENTAL SYMPOSIUM

The First Annual Medical Department Symposium for Combined Armed Forces Medical Department Reserve Officers under the auspices of the Commandant Fifth Naval District will be held at the U S Naval Hospital Portsmouth Va 16-18 October 1957 "Advances in Operational Military Medicine" will be the theme of the three-day program

The meeting on the first day will be conducted at the U S Naval Hospital Portsmouth with a special afternoon program at the U S Naval Dental Clinic Naval Station Norfolk Va for members of the Dental Corps There will be separate meetings for members of the Nurse Corps and of the Medical Service Corps On the second day a meeting at the Fleet Training Center U S Naval Base Norfolk will be highlighted by a talk on "Advances in Medical Defense Against Thermo-nuclear Injuries" by Rear Admiral Charles F Behrens MC USN (Ret) Lectures on the third day will be given at the U S Naval Hospital Portsmouth

Among the prominent guests and speakers on the opening day will be Major General James P Cooney Deputy Surgeon General of the Army Rear Admiral Francis M Hughes Commandant Fifth Naval District Rear Admiral O B Morrison Jr District Medical Officer Fifth Naval District Captain Glenn W Berry DC USN District Dental Officer Fifth Naval District Captain Donald J O'Brien MC USNR Director Naval Reserve Division Bureau of Medicine and Surgery Department of the Navy Captain W Leona Jackson NC USN Director Nursing Division Bureau of Medicine and Surgery Department of the Navy Colonel Inez Haynes ANC Chief Nursing Division Office of the Surgeon General Department of the Army and Lieutenant Colonel Grace J Hayden USAF (NC) Command Nurse Headquarters Continental Air Command U S Air Force

Retirement point credits will be awarded to those in attendance who are on the Active Status List in the Armed Services Reserve Program provided they register with the authorized military representative assigned the duties of recording daily attendance

Programs and additional information may be obtained by addressing the District Medical Officer Fifth Naval District Naval Station Norfolk Va

## DEWITT ARMY HOSPITAL DEDICATED AT FORT BELVOIR

The second of nine new hospitals planned for the Army during the current building program was formally dedicated as DeWitt Army Hospital, named in honor of Brigadier General Wallace DeWitt MC, USA, on 26 June 1957 at Fort Belvoir, Va. This new, multistory, 250-bed hospital which can be expanded to 500 beds with the construction of two additional wings, cost approximately 4½ million dollars, excluding equipment and epitomizes the latest thinking in the design and construction of hospitals. The structure is of a contemporary style of architecture replacing a rambling series of World War II cantonment type frame buildings. It is constructed along highly functional lines, and features centralized clinics, an audiovisual call system, a central dictation network, a 46-station pneumatic tube message carrier system, and other modern innovations. Colonel Charles L. Kirkpatrick, MC USA, is the present commanding officer.

A short dedication ceremony was held in the main lobby where a portrait of the late General DeWitt and a dedicatory plaque were unveiled by General John DeWitt. The plaque reads as follows:

1957  
DEWITT ARMY HOSPITAL  
FORT BELVOIR VIRGINIA  
Named In Honor of  
BRIGADIER GENERAL WALLACE DEWITT  
MEDICAL CORPS UNITED STATES ARMY  
1878-1949

The main ceremony was held in a wooded area directly across from the new hospital. Major General Silas B. Hays, Surgeon General, United States Army, gave the dedication address. Speaking to a group of distinguished visitors which included members of the DeWitt family, Major General Dan C. Ogle, Surgeon General, United States Air Force, and Major General David H. Tulley, USA, Commanding General, U. S. Army Engineer Center and Fort Belvoir, General Hays paid great tribute to the officer in whose name the hospital was dedicated, saying:

We are here today to dedicate a hospital. I would be the last to say that the quality of medical service depends primarily on the quality of the physical plant in which it is housed. Primarily it depends on the professional competence and enthusiasm of the people comprising that service. On the other hand, I would not say that the physical plant has no effect on the quality of medical service. Here at Fort Belvoir you have had an excellent medical serv-

ice in spite of undesirable buildings. I have great confidence that you will have an even better medical service now that you have this wonderful new hospital on your post. I know both the patients and the staff will be happier and prouder.

*The newly dedicated DeWitt Army Hospital, Fort Belvoir*

DeWitt Army Hospital continues a new tradition in the Army Medical Service. Heretofore we have had named hospitals and "post" or station hospitals. As our new permanent post hospitals are completed and put into operation, we plan to name each one. It is appropriate that the newest of our Army hospitals bears the name of one of the most outstanding medical officers in our Army's history, Brigadier General Wallace DeWitt. It is most proper also to note that this occasion marks the second time the Army and the Army Medical Service have saluted the name of DeWitt in this manner. In February 1944 when the Army activated a General Hospital at Auburn, Calif., it was named in honor of Brigadier General Calvin DeWitt, father of the outstanding medical officer we are here to honor today.

Throughout the history of our country, the United States Army has furnished many of our greatest public leaders. In like manner, the Army Medical Service has had the good fortune to list among its members medical men whose skills and abilities gained national recognition—to name only a few, Beaumont Letterman, Gorgas, Sternberg, Walter Reed, Kell, Craig Simmons, and Irvin. Included in any list of our illustrious Army medical men must be the medical officer in whose name we dedicate this hospital today, Brigadier General Wallace DeWitt.

It is not my intention here today to review General Wallace DeWitt's life or to list his accomplishments and the honors that were accorded him. All of these are a matter of record shining brightly on a special page of the Army Medical Service's history. I do believe it is fitting to note some of the highlights of General DeWitt's life in order that you may also come to appreciate his abilities and understand why we are naming this hospital for him.

General DeWitt was born in 1878 at Fort Steele, Wyo., the son of an Army officer. His father served the Army for 49 years as an infantry and later as a medical officer. General DeWitt received his M. D. degree from the University of Pennsylvania in 1900 and entered the Army the same year as a contract surgeon. His first assignment was in the Philippines and included action in several expeditions as well as duty on the island of Corregidor.

Reading left to right: Major General David H. Tulley, USA, Commanding General, U. S. Army Engineer Center and Fort Belvoir; General John DeWitt, USA (Ret.); Mrs. Ruth Blanchard; Major General Silas B. Hays, Surgeon General, U. S. Army; Mrs. Calvin DeWitt; Brigadier General Calvin DeWitt, USA (Ret.); and Major General Dan C. Ogle, Surgeon General, U. S. Air Force.

In World War I he was Surgeon of the 83d Division and then joined the Vth Corps as Chief Surgeon, serving in the St. Die section in the First Army Sector and participating in the Meuse-Argonne Offensive.

Returning from France in 1919 he was assigned to Fort Thomas, Ky., and Fort Sam Houston, Tex., after which he was assigned to Letterman General Hospital in San Francisco. He became professor of military hygiene and post surgeon at the United States Military Academy at West Point in 1931, remaining at that post until named head of the Walter Reed Army Medical Center in 1935. In December of that year he was appointed Brigadier General Assistant to The Surgeon General, a post he held until 1939.

He again assumed command of Letterman General Hospital in 1940. Required for age in 1942, he was immediately recalled to active duty because of our entry into World War II. He became port surgeon, San Francisco Port of Embarkation, and served with his usual distinction in that assignment until ill health caused him to retire in 1945.

Failing strength severely limited his activities following retirement and the loss of his beloved wife in the year of his retirement affected him most deeply. General DeWitt died in December 1949 at Letterman Army Hospital where he had passed many happy and successful years and he was buried in Arlington.

General DeWitt was a man who loved and who followed the highest precepts of the doctor and the soldier service to his country the healing of human ills the instruction of youth His devotion to his chosen profession of healing and his dedication to duty were the hallmarks of his noteworthy service to the Army the medical profession his country and his fellowman.

Standing before portrait of the late Brigadier General Wallace DeWitt MC USA are (left to right) Major General David H. Tulley Major General Silas B. Hays and General John DeWitt (center)

We are pleased to have with us today General DeWitt's brother General John L. DeWitt (retired) his brother Brigadier General Calvin DeWitt (retired) and his sister Mrs. Robert M. Blanchard widow of an Army officer. It is not often that we have an entire family whose life has been and is so closely related to the Army. I know that all of them treasure this moment and that the memory of this occasion will be cherished with the many other memories they have of the distinguished brother and his contributions to the nation as an Army medical officer. I know all of us are glad that so many members of this great DeWitt clan are able to be with us today and join us in honoring one of the greatest members of their illustrious family. I know all of you join with me in the wish that this occasion will provide one more proud and happy memory for all of them.

General DeWitt received countless commendations for his professional skill and administrative ability during his long career. His reputation is already secure, yet I believe this fine new building will make certain that his unquestioned brilliance is properly memorialized in our time.

Both the Army Medical Service and Fort Belvoir have reason to be proud to dedicate this hospital today to a man who gave of himself to the Army as completely and as selflessly as did General Wallace DeWitt.

---

## Legion of Merit to Three Air Force Officers

The Air Force recently awarded the Legion of Merit to Major General William H. Powell, Jr. and Colonels Marsh R. Halbouty and Robert A. Patterson USAF (MC) for exceptionally meritorious conduct in the performance of outstanding service.

General Powell, former deputy surgeon general of the Air Force and now senior medical officer at SHAPF, was cited for his "significant efforts as a military leader and physician in raising the United States Air Force Medical Service to an unprecedented level of professional competence with its resultant contribution to the operational capability of the Air Force."

Colonel Halbouty's "outstanding professional and administrative skill" were instrumental in making noteworthy contributions to the Air Force Medical Service mission while he was wing surgeon and hospital commander at Ellington Air Force Base, Tex. He is now commander of the U. S. Air Force Hospital, Itazuke Air Base, Japan.

Colonel Patterson was commander of the U. S. Air Force Hospital, Madrid, Spain, from 24 August 1954 to 27 December 1956, where he "demonstrated outstanding initiative and creative imagination in locating, equipping and maintaining a compact, modern medical facility able to provide excellent medical care for military personnel in Spain and by his professional competence, tact and extensive knowledge of medical problems, gained the assistance and cooperation of the local medical authorities." He has been reassigned to Stewart Air Force Base, New York, as surgeon of the Eastern Air Defense Force.

## SYMPOSIUM ON MILITARY MEDICAL PROBLEMS AT INTERNATIONAL COLLEGE OF SURGEONS CONGRESS

Medical problems of the Navy particularly those arising out of an atomic age will be considered in a Navy Symposium that will feature the scientific program at the 22d Annual Congress of the United States and Canadian Sections International College of Surgeons in the Palmer House Chicago Ill 8-12 September

The symposium will be presented on the morning of the final day it was announced by Vice Admiral Ross T McIntire Chicago executive director of the International College of Surgeons Admiral McIntire said that the following naval officers from Washington will participate

Captain Harry J Alvis Director of the Submarine Medicine Division Bureau of Medicine and Surgery Submarine Medicine in the Nuclear Age

Captain James A Brimsoo Head of the Atomic Defense Branch of the Special Weapons Defense Division Bureau of Medicine and Surgery Hazards of Ionizing Radiation to Military Medicine

Captain Gerald J Duffner Medical Officer of the Experiment 1 Diving Unit Naval Gun Factory Medical Aspects of Recent Trends in Diving

Captain William M Soowdeo Head of the Special Activities Branch of the Aviation Medicine Division Bureau of Medicine and Surgery Newer Concepts of Aviation Medicine

Lieutenant Commander John H Ebersole Medical Officer aboard the U S S *Seawolf* nuclear-powered submarine Problems of Radiologic Safety Associated with Seagoing Nuclear Reactors

The scientific program of the congress will cover all phases of surgery The speakers will include world renowned surgeons from four other continents as well as from the United States Canada and Mexico

# ANNUAL MEETING OF MILITARY SURGEONS IN WASHINGTON, D C , OCTOBER 28 30

"Professional Excellence—The Criterion of Military Medicine" will be the theme of the 64th annual convention of the Association of Military Surgeons of the United States, which will be held at the Statler Hotel, Washington, D C , on October 28 to 30 1957. In addition to the program listed below, meetings of the dental, nurses, veterinary, medical specialist, and sustaining membership sections will be held.

## Monday Morning, 28 October

## Reviews of Recent Books

**THE TREATMENT OF BURNS** by *Curtis P. Artz* M D F A C S Lt Col MC USA (Ret), and *Fritz Retts* M D 250 pages 199 illustrations on 105 figures Illustrations by *Burr Bush* W B Saunders Co Philadelphia Pa, 1957 Price \$7.50.

This short concise but extremely informative text covering particularly the detailed management of burns is a highly welcomed volume to the medical literature. The vast experience and authoritative knowledge of the authors plus the clear readable style of the text will find this volume being referred to frequently by all physicians responsible for the care of the burned patient. The organization of the material makes for rapid easy reference. The detail of information is sufficient to satisfy the most critical reader. The basic pathophysiologic concepts involved are adequately reviewed. Conflicting points of view are clearly expressed. The choice of therapeutic armamentarium is based on a well-established scientific foundation. As an example, the authors identify clearly the occlusive dressing and exposure method in the treatment of burns as distinct from and not to be confused with such terminology as open or closed management since the aim of both occlusive dressing and exposure method is similar namely, the accomplishment of a dry protective covering. Neither method is completely ideal and frequently one should complement the other. The authors are to be commended for the Herculean task of bringing together in a most acceptable form the extensive world writings on this most formidable surgical problem. This volume should find itself in the personal library of all who accept the responsibility for the treatment of burns.

—DAVID GOLD Col USAF (MC)

**PRINCIPLES OF UROLOGY** An Introductory Textbook to the Diseases of the Urogenital Tract by *Neredith F. Campbell* M S M D F A C S 622 pages 319 figures W B Saunders Co Philadelphia, Pa 1957 Price \$9.50

This book was written by Doctor Campbell who is one of the foremost urologists of our time to serve a twofold purpose for the instruction of the student in the broad fundamentals of urology and as a practical guide for the physician who is not a specialist in urology. To accomplish this the author has omitted controversial points unlikely theories, and detailed descriptions of major procedures such as are usually found in standard texts on this subject and has described in detail in a concise and easily understandable fashion all of the aspects of urology that are of value to the groups for whose use the book is intended.

The subject matter is extremely well covered and only widely accepted and up-to-date diagnostic and therapeutic procedures are presented. This book is replete with illustrations (photographic and artistic) and diagrammatic tables of the highest quality which serve further to enhance its value. Outstanding among the tables presented are those on the "Embryonic Derivations of the Urogenital Analage" in chapter 6 and "Fluid Administration" (adults and children) in chapter 7. At the end of the book Doctor Campbell has included a section on questions arranged according to chapters which gives the page reference numbers for the answers thereto. This affords an unusual and extremely desirable method for review of the subject matter particularly for examination purposes. In keeping with the rest of the book the bibliography and index are of the highest quality.

This book will be of inestimable value to physicians without specialized urologic training in the management of patients with actual or suspected urologic diseases and defects in regard to both proper diagnosis and treatment including such procedures as urethral catheterization, the passage of urethral sounds and minor surgical procedures. It is strongly recommended also for all students including those at the resident level.—MARK S. CURTIS Capt AC USN

**SYNOPSIS OF GASTROENTEROLOGY** by Rudolf Schindler M D F A C P  
395 pages illustrated Grune & Stratton Inc New York N Y 1957  
Price \$7.75

This book is a most inclusive synopsis of diseases in the field of gastroenterology for its size written without any excessive verbiage and in a most readable style. Dr. Schindler presents this book for the general practitioner as well as the specialist in internal medicine.

One of the reasons that it is a most useful book is that it is a personal summary in the practical diagnosis and treatment of gastrointestinal disorders. The author has presented us his diligent experiences of more than 35 years of practice in this field. There are no references in this book except for the general acknowledgment of five or six standard textbooks in the field of gastroenterology and associated radiology. The book is divided into 17 chapters beginning with a discussion of gastrointestinal lesions and symptoms connected with diseases of other organ systems and closing with a presentation of general therapy of gastrointestinal diseases.

In the over-all presentation of material the general etiology and symptoms of gastrointestinal disorders is discussed. The author then covers in concise form the various pathologic conditions and their treatment affecting the gastrointestinal system from the mouth to the rectum. Since Dr. Schindler has been one of the pioneers in the use of a gastroscope he states that if the clinical history is suggestive of disease of the stomach a doctor cannot say that a certain patient has no organic disease even if x ray and other studies are absolutely negative unless he also has done a gastroscopic examination. He admits of course that even a gastroscope has its limitations but it does supple-

ment the radiologicalexamination of the stomach. He also maintains that when gastrointestinal disease is suspected that in addition to a detailed history and physical examination the other studies must include fluoroscopy of the esophagus and x-ray of the entire gastrointestinal tract including a barium enema and a gallbladder series. D. Schindler may be overemphasizing laboratory and x-ray procedures but in the individual patient all these procedures must be considered if the patient's symptoms suggest disease. He emphasizes the importance of a detailed carefully performed physical examination, and comments that even though a patient may seem to have no organic disease he should not be told that there is "nothing wrong with him" but should be told that "no disease has been found as a result of all these thorough examinations and tests."

This synopsis of gastroenterology is an up-to-date book, and carefully compiled as a practical reference volume for the hospital resident as well as the internist and general practitioner. Other volumes would have to be consulted for theoretical concepts and discussion of controversial aspects of gastroenterology. This book is highly recommended for any hospital or private professional library.

—U. R. WHITKASAS Col MC USA

**CLINICAL ELECTROCARDIOGRAPHY** *Interpretation on a Physiologic Basis*, by Samuel Gardberg M.D. with Chapters by Richard Ashman Ph.D., Irving L. Rosen M.D. and Louis Levy II, M.D. 315 pages illustrated. Paul B. Hoeber Inc. Medical Book Department of Harper and Brothers New York N. Y., 1957. Price \$12.75.

The stated purpose of this 315 page profusely and well illustrated text is to present the physiologic principles upon which electrocardiography is based and to demonstrate by visual means the electrocardiographic alterations that are produced by physiologic as well as pathologic variations. The author and the contributors to this text have succeeded in accomplishing this goal. The conventional standard limb leads and unipolar limb leads are illustrated as a projection of the derived spatial QRS loop and the precordial leads by the solid angle method. A simple means of utilizing a model spatial QRS loop projected upon the frontal plane is used as an effective teaching aid. The major value of this book is the clear presentation by these means of the changes of the QRS and T deflections that result from normal variations particularly those of cardiac position. Adding greatly to its worth is the contribution of Richard Ashman who presents a clear and concise discussion of the mechanisms of A-V conduction disturbances and the arrhythmias.

It is unfortunate that the established clinical value of the precordial leads is minimized by the author. The use of multiple precordial leads is not adequately discussed and the value of exploratory leads ignored. An almost total reliance on the use of the limb leads by construction of a frontal plane QRS-T loop is the major defect in this otherwise excellent presentation. Another deficiency is that interpretation of P wave variations is neglected. Issue might also be taken with the

interpretation given to ST T wave variations although the author admits that proper evaluation usually depends upon the experience of the observer

In summary this book should not be considered a reference text for all the problems encountered in electrocardiographic interpretation. Rather its value lies in the clear method of presentation of the basic concepts which will properly orient the beginner emphasizing the hazards of empiricism to those more experienced while to the teacher it offers a method whereby the physiologic principles of electrocardiography may be effectively presented

—LOREN F PARNLEY Lt Col MC USA

MODERN TRENDS IN GERIATRICS edited by William Hobson B Sc M D D P H 422 pages illustrated Paul B Hoeber Inc, Medical Book Dept of Harper & Bros New York N Y 1957 Price \$13.50

This British publication composed of 17 chapters on carefully chosen topics is a fairly comprehensive review of gerontology with an adequate bibliography for each subject. The first chapter gives one a good perspective as to the current and anticipated impact of aging as shown by the estimate that 20 per cent of the British population will be eligible for pension by 1980 (similar to the trend in the United States). This is followed by objective evaluation of aging by biologic biochemical and psychologic measurements. The specific and detailed discussions of the basic diseases of the aged are interesting. The term *chronic bronchitis* appears to be similar to what is called *pulmonary emphysema* in the United States.

This text adequately summarizes the positive approach and optimism one must acquire in the total care and rehabilitation of the aged. It should be of particular value and interest to internists, general practitioners and social service workers both in Britain and in the United States — JOHN B MacGREGOR Capt MC USN

ATLAS OF CLINICAL ENDOCRINOLOGY including Text of Diagnosis and Treatment by H Lissner A B M D and Roberto F Escamilla A B M D 476 pages 148 plates including 3 in color The C V Mo by Co St Louis Mo 1957 Price \$18.75

As the authors state there are many excellent textbooks of endocrinology well illustrated but still presenting the subject primarily by the written word. Intending this to be an atlas of practical endocrinology for clinicians the authors use the welcome pictorial approach. Drawing mainly from their extensive source of patients at the University of California School of Medicine clinics and supplementing it where necessary with sketches or loaned photographs they present an amazingly complete coverage of the endocrinopathies in less than 500 pages.

The typical case photographs taken serially when progression or response to treatment is pertinent make an indelible imprint on the reader's memory coming as close to bedside rounds as literature can. Concise case histories add to the vivid portraits so that any observant

clinician not particularly schooled in endocrinology, should be guided to proper diagnosis. To complete the subject coverage laboratory findings and charts of endocrine development norms are included, but the emphasis is kept clinical.

It is refreshing to have the authors present their specific recommendations as to case management rather than merely list the possible therapeutic programs, which often leave the less experienced physician in a maze of indecision. Certainly Doctor Lissac and Lissac will have every right to speak with authority, and their opinions are of infinitely more value than any compiled list of alternatives.

This beautifully presented atlas is a welcome and most heartily recommended addition to the library of every clinician and is an absolute necessity for the practicing endocrinologist. Despite the hundreds of excellent photographs, some in color, the price of the atlas is within the general range expected for good medical textbooks.

—FRANCIS G. SOULE, Jr. Capt. MC USA

**BLOOD AND BONE MARROW PATTERNS** by C. D. Talbot, M. D., Elmer R. Hunsicker, B. S., and Jonah L. M. D. 39 pages, illustrated with 145 colored photomicrographs. Crane & Stratton, Inc., New York, N. Y. 1957. Price \$12.

This book departs from the usual publications in the field of hematology in that it presents blood and bone marrow patterns along with cell morphology. The blood cell series and the cell patterns of the various disease states are included in the book.

A brief description of each cell appears on the page facing the photograph of that cell, thus linking description and cell. This eliminates searching the text in an effort to link the two, a common fault of many of such textbooks.

The photomicrographs, all in color, can only be spoken of in superlatives. They are truly outstanding. The authors are to be commended for their fine work. No other text in the field quite equals this one in this respect.

Clinical data is not included and none is necessary if the book is used as it should be—as an adjunct to a good standard textbook of hematology.

The Atlas is of value to the teacher as well as to the student. It is almost a must for the general practitioner who wishes to make a diagnosis and follow his own cases of this type. The book should be in the library of every physician who has an interest in the field of hematology.

—WILLIAM C. DUNNINGTON, Lt. Col. MC USA

**FUNDAMENTALS OF MICROBIOLOGY** by Martin Frobisher, Sc. D. 6th edition. 617 pages, illustrated. W. B. Saunders Co., Philadelphia, Pa. 1957.

This is a new edition of a reliable textbook covering the entire field of microbiology. Designed for college students who are not necessarily specializing in microbiology, the book has been written in a most

interesting and readable style and covers viruses tickettsiae and fungi as well as bacteria Physicians wishing to review the basic fundamentals of the field of microbiology especially the more recent changes will find the book an excellent one

The references at the end of each chapter are current and while many important individual references to classical papers have been left out the author has made provisions to cover this minor fault by including references to textbooks and review papers covering the earlier more classical work

The author has drawn generously from many sources an excellent collection of photographs to supplement his readable text the combination producing a very clear concise and accurate survey of microbiology This is a textbook that should find a place in the library of anyone interested in keeping up with the latest advancements in this field —DAVID F HERSEY Capt USAF (MC)

**PERINATAL LOSS IN MODERN OBSTETRICS** by Robert E L Nesbitt Jr M O A Series of Monographs in Obstetrics & Gynecology edited by Claude E Heaton M D 432 pages 108 illustrations including 10 in color F A Davis Co Philadelphia Pa 1957

Until recently perinatal mortality has not received the interest or attention of maternal mortality Drawing from his clinical and pathologic experience at Johns Hopkins University Dr Nesbitt now gives us a reference volume on perinatal loss

The first portion of the book deals with statistical analysis and classification based upon the groupings of the World Health Organization i e early fetal death intermediate and late fetal death and additionally includes a section on prematurity The second portion covers specific causes of fetal death i e anoxia birth injury malformations infections hemolytic disease multiple gestation ectopic gestation analgesia and anesthesia and factors in prevention of perinatal loss The appendix contains a perinatal mortality code sheet valuable for conference use

This new volume is a readable well illustrated thorough survey of this important subject which includes new and original work in addition to an extensive and usable bibliography It is required reading for obstetricians pediatricians and pathologists

—WILLIAM C HERNQUIST Lt Col USAF (MC)

**CLINICAL NEURO-OPHTHALMOLOGY** by Frank B Walsh M D F R C S (Ed) D Sc (W A Hon) 2d edition 1293 pages illustrated The Williams & Wilkins Co Baltimore Md 1957 Price \$29

This book is the most complete publication on the subject of neuro-ophthalmology in print today The chapters are well organized to allow the reader to quickly refer to the type of case in mind The individual diseases discussed are well outlined yet in sufficient detail to give the reader a clear concise resume of the history signs symptoms and

pathology of each condition described. The style of writing stimulates the reader's interest to follow the discussion to completion. The abundance of reference material cited at the end of each disease described gives authenticity to the statements made. The author gives full credit to previous writers in instances wherein his own experience with a particular condition is lacking.

This volume provides the experienced ophthalmologist with a ready reference to any particular type of case and at the same time affords the less experienced the opportunity to study neuro-ophthalmologic conditions as part of a group. The illustrations are numerous and have been chosen well to depict the typical conditions described. The chapter on "Tumors and Related Conditions" is considered to be one of the best presented sections of the book. The inclusion of a paragraph on treatment in many of the conditions described adds greatly to the value of this work as a reference book.

—JACK H. BRISTOW, Col. USAF (AC)

**THE YEAR BOOK OF THE EYE, EAR, NOSE AND THROAT (1956-1957 Year Book Series)** The Eye, edited by Derrick Vail, B. A., M. D., D. Oph. (Oxon.); F. A. C. S., F. R. C. S. (Hon.). The Ear, Nose and Throat, edited by John R. Lindsay, M. D. 448 pages, illustrated. The Year Book Publishers, Inc., Chicago, Ill., 1957. Price \$7.

This outstanding edition of the Year Book series presents impartially selected condensations of the more leading and timely articles relating to the eye, ear, nose and throat from the World's journals received between October 1955 and September 1956.

Of the book's 448 pages, half are devoted to ophthalmology, which is further divided into 11 major headings. The ENT section is arranged within 14 groupings. The masterfully selected articles are of significant importance in describing and explaining the newer diagnostic and therapeutic approaches to the problems of eye, ear, nose, and throat.

Both the eye and ENT sections are replete with excellent diagrams, charts, and illustrations. The editorial supplements reflect the vast experience and status of the commentators, adding to the interest and interpretation of the articles.

The printed slip of 23 questions on the articles in the book should be made a permanent page at the end of the volume. The index, both by subject and author, is of value in using the book as a reference. The volume is a must for every physician interested in ophthalmology and otolaryngology. Inasmuch as these specialties must be considered mature and independent, many interested physicians will be glad to note the replacement of the 1957-1958 series of the Year Book of Eye, Ear, Nose & Throat by two volumes, one, *The Year Book of Ophthalmology* and the other *The Year Book of Ear, Nose and Throat* (including a section of maxillofacial surgery).

—LE ROY E. WIBLE, Capt. MC, USN

MODERN OPERATIVE SURGERY in Two Volumes Volume II edited by the late G Gey Turner LL D D Ch M S F R C S F R A C S and Lambert Charles Rogers V R D M Sc M S F R C S F R C S E F R A C S F A C S with a foreword by Sir Gordon Gordon Taylor K B E C B M A LL D Sc D M D M S F R C S F R C S E F R C S I F R A C S F A C S 4th edition 2 614 pages illustrated Paul B Hoeber Inc New York N Y 1957 Price \$17 50

This work of 38 contributors from the British Empire covers the whole field of operative surgery and the surgical specialties The virtue of having basic information concerning every facet of the field of operative surgery is offset by the fact that in many details obsolescence has already set in before the reader gets the book The bulk of the book is standard material that has permanent value The tremendous amount of work that went into preparing this work is partially wasted because it has lost the freshness and newness that would make possession of the set a delight to the owner

Examples of the outdated of some material are Diphtheria offers the widest sphere of usefulness (for tracheotomy) The dressing (for laryngectomy) should be just tight enough to give a slight cyanosis of the lips and the ears "Herniotomies are kept in bed for 21 days postoperatively Use catgut in tying off omentum because omentitis sometimes follows the use of silk In the section on Rectum and Anus it is stated that 12 percent of the fistulas in ano are tuberculous Colon preparations are of streptomycin and a sulfa drug and newer preparations are not mentioned These are typical examples of differences from common practices and experiences in this country Certain practices of British physicians are noted by innuendo such as that of otologists to do the surgery on otogenic brain abscesses is an example Another is the specific comment that in excision of an eye everyone wears rubber gloves

The most interesting and helpful parts of this work are in the philosophies expressed as in excerpts from Gordon Grey Turner's introduction The measure of surgical skill is efficiency The correct operation clumsily performed is much more likely to be successful than the wrong operation no matter how brilliantly performed In discussing the operability of certain malignant lesions he quotes

The abyss is worth a leap however wide  
When life sweet life is on the other side

The book is mechanically well done it is well indexed anatomic descriptions are uniformly excellent and lucid and footnotes give bibliographic references and occasional editorial annotations The references are usually hallowed with age The print is of a size to permit the mature surgeon to read it with ease The quantity of material the extremely wide but somewhat outdated coverage of a vast subject the detail expressed and the cost however make it probable that most busy surgeons or students will not take the time to read nor assume the expense to own this work —DON S WENGER Col USAF (MC)

**SURGERY: Principles and Practice** by J. Carroll Allen, M. D., Henry A. Harkins, M. D., Ph. D., Carl A. Weaver, M. D., and Jonathan E. Heflat, M. D., D. SC. (Med.) with 32 contributors. 1495 pages, 673 illustrations. J. B. Lippincott Co., Philadelphia, Pa., 1957. Price \$16.

The most severe criticism that could be made of this weighty tome (8 pounds, 1495 pages) is that perhaps it attempts to do too much for too many. Possibly it should be divided into two or more volumes for ease of reading and for its value to the student for the principle of surgery and its value to the surgeon in the practice of surgery, although it often is difficult to draw the line between the principles and the practice. The book is written in clear, concise, grammatical English (which is not found too frequently) and the illustrations for the most part are really explanatory. Chapter 1, "The Philosophy of Surgery," should be required reading for every premedical and medical student, while the older surgeon will find in it an excellent restatement of his credo as originally defined by Hippocrates.

The portion on principles of surgery takes up topics of wound healing, fluid balance, chemistry, physiology, anatomy of the systems, treatment of burns, electrolyte balance and blood transfusions. The dangers and abuses of the latter are well stated. This portion is written with authority and attractively presented so much so that it is difficult to stop reading once one has started.

The section on the practice of surgery is amazing in the amount of ground that it covers and the excellent manner in which this is done. Practically all the systems and specialties are dealt with in detail. The articles on the stomach, intestines, pancreas, spleen, adrenals, and liver, with their many diseases and the differential diagnoses of their various dysfunctions are comprehensive, complete, and authoritative. The specialties also are well represented with excellent sections on orthopedics, both traumatic and nontraumatic, and thoracic, abdominal, genitourinary, gynecologic, and plastic surgery. The article on hernias is very good, although in my opinion the author is too much inclined to favor the Cooper's ligament repair, which has not had sufficient time to prove itself so far as late recurrences are concerned. Some of the illustrations in this section lack the clarity displayed by others in the book. In the section on plastic surgery, there is an error in labeling C and C prime in figure 477A on page 1180. This would alter the technic of the operation described, if one were not aware of it. Otherwise this portion of the book is well worthwhile.

Many articles of great value that are not found in most books on surgery are included in this volume. I refer particularly to the sections on surgery of the hand, surgery of pulmonary tuberculosis, peripheral vascular surgery, and pediatric surgery. At long last we have an excellent presentation of the latter as differentiated from surgery of the adult. The division on military surgery is most timely and well done.

Malignant tumors are discussed as a whole and as found in each system of the body, along with the surgery, radiation therapy (advan-

tages and dangers of) and current chemical and endocrine factors used for their curative or palliative qualities

This is the finest book on the subject of the principles and the practice of surgery that has been published. It will be of great value not only to the medical student, intern and resident but also to the actively practicing surgeon who wants a rapid review of the principles and techniques of the more commonly performed operations. Certainly it should be in every medical library and I am sure that a great many surgeons will find it indispensable.—**LAWRENCE L. BEAN** Capt MC USN

**THE YEAR BOOK OF ORTHOPEDICS AND TRAUMATIC SURGERY (1956-1957 Year Book Series)** edited by *Eduard L. Compere* M D F A C S F I C S 336 pages illustrated The Year Book Publishers Inc Chicago Ill 1957 Price \$6.75

As in the past this volume should be of interest to surgeons in general and orthopedic surgeons in particular as a concise review of pertinent current orthopedic literature. Representative orthopedic articles published in medical journals between November 1955 and November 1956 are abstracted in a clear and well written manner. The illustrations are well reproduced and the editorial comments are thoughtful. The articles are selected and grouped to reveal current trends in this field. Up-to-date information is presented regarding such timely problems as geriatrics and osteoporosis, nonunion of fractures, internal fixation of fractures, bone grafts and bone banks, treatment of tuberculosis, intervertebral disk lesions, whiplash\* injuries, treatment of arthritis, and use of antibiotics. The volume provides a good reference work for a more detailed study of the original article.

—**EARL W. BRANNON** Lt Col USAF (MC)

**SURGICAL GYNECOLOGY** Including Important OBSTETRIC OPERATIONS *A Handbook of Operative Surgery* by *J. P. Greenhill* M D Illustrated by *Agela Bartnach* 2d edition 377 pages illustrated The Year Book Publishers Inc Chicago Ill 1957 Price \$9.50

This monograph in atlas form is written expressly for the student gynecology resident and general practitioner who does occasional gynecologic surgery. The text is easily understood and is excellently supported by 107 pen and ink plates.

The book is divided into four major sections, the first of which is on Preoperative Preparation and Postoperative Care and Complications. These are presented adequately and the section is well worth reading by anyone doing pelvic surgery. The other sections deal with Vulvar and Perineal Operations, Vaginal Operations, and Abdominal Operations. In these sections the author has included all the usual gynecologic procedures plus some urologic and general surgical procedures for repair of bowel and urinary tract injuries resultant from operations in the pelvis. In general the book is well organized and very easily assimilated. It is a must for all students and residents in gynecology but will not materially aid the specialist in this field.

—**WILLIAMS BAKER** J Capt MC USN

1957 MEDICAL PROGRESS, A Review of Medical Advances During 1956, by Morris Fishbein, M. D. 367 pages. The Blakiston Division, McGraw-Hill Book Co., Inc., New York, N. Y. 1957. Price \$6.

Again the editor has succeeded in publishing, in concise readable form the best from the 1956 medical literature. Ably assisted by 20 contributors, who for the most part are well known in their respective fields, the outstanding advances and achievements during the year are reported on entire subjects such as general aspects to single disease entities such as diabetes by the famed D. Elliot P. Jordan.

There is little to be criticized in the volume with the possible exception of too much space being devoted to subjects of restricted interest. For those who seek a quick source of information covering recent advances the book is valuable and for those who wish to cover a subject more extensively, the bibliography is very complete. It is manifestly impossible to pay tribute to each investigator and each achievement recorded within the year as time and space will not permit.

—MIRIAM L. DISSELHOR, Col. A.C.L.S.

THE LEUKEMIAS, Etiology, Pathophysiology, and Treatment, edited by John W. Rebuck, Frank H. Hellbell, and Raymond W. Monto. A Henry Ford Hospital International Symposium. 711 pages, illustrated. Academic Press, Inc., New York, N. Y. 1957. Price \$13.

This is a comprehensive, up-to-date volume on the leukemias. It consists of an edited collection of papers presented at the International Symposium on the Leukemias, Etiology and Pathophysiology, held at the Henry Ford Hospital, Detroit, Mich. 8-10 March 1956.

The work represents the efforts of 57 participants. All are outstanding authorities on the leukemias and related entities. The majority of the contributors are from the United States. England, Canada, France, Denmark, Italy, and Switzerland are represented by leading individuals in the field. There are 39 chapters divided into eight general areas of discussion as follows: the leukemic cell, its structure and antigenicity; genetic and environmental factors in the transmission of leukemia; radiation biology of leukocytes, the leukemias and the malignant lymphomas; leukocytic physiology; metabolism of amino and nucleic acids in the leukemias; further biochemical considerations in the leukemias; and nucleic acids as the target for chemotherapy; mechanisms of drug action and resistance.

As pointed out in the preface, this volume gives the present complex position of leukemic etiology and pathophysiologic disturbance, a much needed knowledge of detailed leukocytic functions and comprehensive thought on the therapy of the leukemias. It establishes the basis of comparison in the earlier works in this field and points up the extensive and accelerated progress made in the last few years.

This book is highly recommended for anyone concerned with physiology or pathology of the leukocytes.

—FRANK M. TOWNSEND, Col. USAF (MC)

PROCEEDINGS OF THE INTERNATIONAL CONFERENCE ON THE PEACEFUL USES OF ATOMIC ENERGY Held in Geneva 8 August 20 August 1955 Volume 11 Biological Effects of Radiation 402 pages illustrated *United Nations Publications* 1956. Distributed by Columbia University Press New York N Y 1956. Price \$8

This volume is one of 16 comprising the Proceedings of the International Conference on the Peaceful Uses of Atomic Energy held in Geneva Switzerland in August 1955. It is not of course arranged as a textbook but for anyone who is acquainted with the fundamentals of radiobiology it is a superb review of the problems with which the science is concerned at the present time. This was to be expected when every country represented picked the best men and the most representative articles for presentation at this meeting.

These articles are for the most part of general interest as compared to the average article in a scientific journal dealing with minute and detailed research into specialized aspects of a subject. Tsuzuki, Japan's leading radiobiologist is the author of "Bio-Medical Effects of Nuclear Energy: the Early Effects of Radiation Injury" and "Injury due to Radioactive Fall out." In this last article which presents the cases of the Japanese fishermen of the fishing boat "Lucky Dragon" who were caught in the fall out of the megaton weapon in March of 1954, it is interesting that Professor Tsuzuki lists first among the causes of the liver disease suffered by these fishermen serum hepatitis caused by repeated transfusions.

Professor Bacq of Belgium who has done an immense amount of work on chemical protection against radiation has an article on this subject but to offset presenting the views of only one man no matter how eminent there are several articles by other authorities on protection by chemical and other means. Muller the Nobel Prize winner presents in a masterly fashion some of the genetic problems posed by radiation in his paper "Radiation and the Genetic Constitution." Looney who has worked for a number of years collecting data on patients who have had radium and thorium administered to them has an article on "Radium and Thorium Excretion in Man." There is an article on the "Effect of Radiation Dose and Shortening of Life Span" by Blair of Rochester in which his concept of the mathematical representation of the relationship between radiation dose and life span is set forth.

Any critical comments are of minor importance and do not detract greatly from the value of the book. In the preface it is stated that editing for style was minimal in the interests of early publication and misprints and incorrect or awkward diction are frequent.

The volume is well bound the paper and printing are of good quality and the photographs are well reproduced. The book is highly recommended to all who are interested in the field of radiobiology.

—JOHN A O'DONOGHUE Capt MC USN

**BRITISH MEDICAL BULLETIN** Volume 34 Number 1 January 1957 213 pages and Pathology of the Kidney 24 pages illustrated Published by the Medical Dept. The British Council London 31 England Distributed by Oxford University Press New York N.Y., January 1, 1957 Price \$3.75

This volume in the series of the British Medical Bulletin is composed of 16 articles dealing with the pathology and physiology of the kidney. The articles are written by a group of clinical investigators, pathologists, radiologists, physiologists, biochemists and medical physicists headed by Professor Robert Platt of the University of Manchester.

Each article is prefaced by an outline of its contents. Physiological principles are discussed in the light of recent research. There are didactic presentation with many references to experimental literature. The reproductions of radiographs and photomicrographs are excellent.

This is a stellar assembly of the latest known facts pertaining to the basic sciences of the kidney unusually well organized and beautifully presented for the residency training program. Not only in urology but other specialties it serves a real and valuable purpose. Multiple sources of information each authoritative are represented. It is exceedingly useful as a library file for reference in looking up specific and special information during the first two years of residency training. The great detail in which the varied subjects are presented will assist the most zealous reader or student. —*FARI C. LOWERY Col MC USA*

**EPILEPSY Grand Mal Petit Mal Convulsions** by *Fetula Fairfield* C. B. 1 M. D. D. P. H. 159 pages illustrated Philosophical Library, Inc. New York N.Y., 1957 Price \$4.75

This small volume appears to be designed chiefly for social workers, teachers, and officials whose duties are concerned with epileptics. However, it is of value to physicians and students who are interested in the problems that arise in the social and economic adjustment of the epileptic child or adult.

The book deals briefly, though adequately enough considering the purpose for which it was written, with the history, diagnosis and treatment of the various forms of epilepsy. It contains a discussion of the various problems that arise in the social or economic adjustment of epileptics in school, the community, or on the job. The problems of institutional care are considered at length and the legal aspects and laws concerning epileptics are discussed. Since the author is British, these problems are discussed from that viewpoint and the various British institutions and agencies available to the epileptic in England are listed. To some degree this makes the book of more immediate value to a worker in Great Britain. Nevertheless, it can be of considerable value to the worker in this country as the author's statements are sound and sensible. The book is simply and clearly written. It is recommended to all those whose work involves the treatment and care of epileptics. —*JAY F. TUTTLE Lt Col MC USA*

HEMORRHAGIC DISEASES by *Armand J Quick* Ph D M D 451 pages  
37 illustrations Lea & Febiger Philadelphia Pa 1957 Price \$9.50

An excellent text for the practicing hematologist and internist. The author's vast experience in the field of blood dyscrasias serves him well in handling an extremely difficult field of many diverse opinions. The scope of the book is comprehensive. Its historical aspects are both delightful and revealing but are marred at times by the author's tendency to emphasize repeatedly his contributions and criticisms. Sustained new advances in the field of coagulation, hemostasis and thrombocytopenia are well described. The method of presentation is effective but occasionally suffers from rambling discussion. Ideas are presented clearly, discussed thoroughly and logically summarized. The bibliography constitutes an excellent compilation of the classics in the field. The second section of the book is devoted to laboratory methods; descriptions are adequately presented and the comments and suggestions will be helpful to those interested in technique. This is an exceedingly good book and is recommended for all interested in the field of hematology — *JOSEPH H ANEROYD* Lt Col MC USA

GOUT by *John H Talbot* A B M D D Sc (Hon) 205 pages illustrated  
Grune & Stratton Inc New York N Y 1957 Price \$6.75

This short but thorough monograph is a complete revision of the author's earlier work "Gout and Gouty Arthritis" which was published in 1953. The present work is replete with illustrative material including graphs, roentgenograms and photographs in color and black and white. The coverage of the subject is extensive and thorough with every imaginable facet of gout represented under chapters dealing with history, definition, heredity, metabolism of uric acid, precipitating agents and many other chapters in addition to the usual ones on diagnosis, differential diagnosis, etiology, et cetera. The bibliography consists of 285 references.

The monograph serves a very valuable function in bringing together in one work all the various metabolic, clinical, therapeutic and laboratory aspects of a much written about but still poorly understood subject. The coverage ranges in its scope from the historical aspects to the latest in research developments. Both theoretical and practical material are integrated so as to aid in the understanding of clinical cases. Therapy of the acute and chronic forms of the disease is very well covered.

I would classify this book as one useful primarily for the internist whether he be rheumatologist or general internist since this disease enters the picture in the differential of every patient manifesting joint abnormalities, kidney failure, renal calculi, albuminuria and even hypertension. Familiarity with this condition is especially important because it is one disease in which we have some measure of controllability amidst so many others considered in its differential for which our armamentarium is so inadequate or futile.

—*DAVID L. DEUTSCH* Lt Col MC USA

LEAHY OF THE 1957

1957

PSYCHOTHERAPY OF THE ADOLESCENT edited by Herma H. Lehman  
M. D. 370 pages International Universities Press Inc. New York  
1957 Price \$5

This book is the outgrowth of a symposium on "The Adolescent" of the American Psychiatric Association in May 1955 at the meeting of the American Psychiatric Association in Atlantic City. Its aim is to provide a reference source for psychologists of the adolescent but in the reviewer's opinion is not a reference book on the subject. One could not for example find specific information regarding the treatment or scope of alcoholism or drug addiction in a teenager's art. It is more useful and much more readable than the usual reference books. Diagnostic categories are easily recognized. The psychiatric problems of adolescents being treated from the standpoint of inpatient or outpatient practice. The reader follows the treatment of a teenager in private practice in private practice plus school practice in school practice plus some inpatient treatment in the outpatient clinic in a pediatrics inpatient service and in an intensive hospital treatment setting. He sees how school teachers can and do handle superficial psychotherapeutic problems as they arise.

The authors in each case are very well qualified to discuss their particular subject, and they draw upon a wealth of experience. Each expresses his opinion freely, unaware of what the other contributors had written. Despite this a surprising unanimity of opinion obtains throughout.

Each chapter and section is illustrated with interesting and informative case summaries. In addition one chapter is devoted to a verbatim psychotherapeutic interview with an adolescent and includes pertinent dynamic comments. Each major section is well summarized and clarified by a discussion. These factors, along with the excellent organization of the book make it extremely readable and interesting and give it a continuity most symposia lack. Adolescence emerges as a much more understandable and less frightening period with which to deal therapeutically. It is seen in broad perspective for a better understanding of its normal developmental phenomena. The authors for the most part deal in specifics rather than generalities so that one can learn a great deal about adolescents and their treatment from this book. Much information emerges that is valuable with regard to preventive measures that can be used during this age period particularly with reference to the role of the school.

This is an extremely readable, informative, concise, relatively brief book that fills a vital need in psychiatric literature and training. The book is highly recommended for anyone doing psychotherapy with this age group and should be of considerable interest to all psychiatrists, psychologists, social workers, pediatricians, general practitioners and others concerned in the teaching and education of this age group.

—DASILE SMITH Lt Col USAF (MC)

DISEASES AND DISORDERS OF THE COLON by Anthony Bassler M D  
F A C P F A C G LL D 217 pages illustrated Charles C  
Thomas Publisher Springfield Ill 1957 Price \$6.75

This book is unique in that it contains no formal bibliography. The opinions expressed in it are largely the author's own viewpoints based on his wide experience and rich store of clinical material gleaned during his many years of practice in a large metropolitan center.

To cover diseases of the colon adequately in 200 pages is an almost impossible task and of necessity many facets of the subject are touched on lightly or omitted entirely. As might be anticipated from one who has lived through many decades of gastroenterologic opinion, the author has formulated many of his own theories on bowel dysfunction and treatment. Some of these are at variance with those currently held. For example, he believes that chilling of the abdomen may be a cause of acute colitis; that infections of the head and throat may be significant in the etiology of ulcerative colitis; and that the terms irritable or unstable colon should be dropped from the medical literature and replaced by "entity names instead." A lengthy chapter is devoted to what the author terms Chronic Biotoxic Intestinal States, which he believes are manifested by such ill-defined symptoms as belching, excessive flatus, fatigue, weight loss, mental depression, abdominal colic or cramping, skin disorders, back and leg pains, excessive passage of mucus, hyperacidity, et cetera. These "biotoxic states," he thinks may be caused by the swallowing of infection from the mouth (sepsis, pyorrhea), throat (infected tonsils), tracheobronchial tract and cranial sinuses, or may result from intestinal stasis, kinks, prosis, bands, et cetera.

Some of the therapeutic measures recommended hark back to bygone days and are no longer generally employed—the treatment of acute appendicitis with sterilized sulfanilamide intraperitoneally, the use of intravenous Mercurochrome and Bergen's vaccine for ulcerative colitis, the administration of Salvarsan, Neosalvarsan, or Mapharsen (no mention of penicillin) for syphilitic ulceration of the bowel and rectum, the giving of thyroid extract for intestinal influenza, and the use of deep x-ray therapy for diverticulitis.

Certain chapters in the book seem to be miscaptioned. The chapter on "Parasitic Diarrheal Infestations" includes the diarrheas due to parathyroid disease, hypoadrenalism, and hyperthyroidism, as well as a section on staphylococcus dysentery. A later chapter entitled "Parasitic Disorders" fully covers parasitic disease of the bowel. The chapter on "So-called Functional States" includes such unrelated subjects as intra-abdominal or visceral injuries, foreign bodies in the intestine, intestinal sand, and enteroliths.

While this book contains much that is valuable for the clinician, it could be greatly improved by careful editing, revision, and consolidation.—EMMETT L. AERHOL, Col. MC USA

**DRUG MECHANISMS AND DRUG ACTION. A Symposium.** Fourth Annual Scientific Meeting of the Houston Neurological Society, Texas Medical Center, Houston, Tex. Compiled and edited by William S. Fields. 147 pages, illustrated. Charles C. Thomas, Publisher, Springfield Ill., 1957. Price \$4.25.

Relatively new drugs, such as reserpine and chlorpromazine have aroused considerable interest in regard to their precise mode of action on the nervous system. Some of the recent basic research attempting to clarify this problem is reflected in this symposium.

How do these drugs accomplish their purpose? Perhaps with this in mind the symposium opened with a presentation of reticular formation neurophysiology. Dr. Robert S. Livingston found that the cortex via centrifugal fibers to the reticular formation may have the capacity to regulate the arousal response and even the content of consciousness. Bearing these connections in mind, it becomes a little easier to understand that drugs acting on the reticular formation may have psychic, emotional or other effects, such as parkinsonism. This is elaborated by Drs. Harold F. Dowditch and Franco Rinaldi, who conclude that these drugs have an upward centripetal or a downward centrifugal effect. By specificity of drug or dosage the upward or downward effects may be those of depression or stimulation.

In an attempt to deal with fundamental units, the neuron and the synapse, Dr. Amedeo S. Marazzi studied the transmission of evoked potentials of these units when influenced by the action and counteraction of various agents including psychotropics, hallucinogens and tranquilizers.

By what selective influence do these drugs act? Dr. Evelyn Killam and Keith F. Killam investigated drug effects on different sites along neuraxial afferent pathways, such as lemniscus, capsule and reticular formation. Dr. Roger Guillemin demonstrated some of the endocrine implications. The broader aspect of certain drug effects on behavior of laboratory animals was explored by Dr. Joseph V. Brady, using the free operant technique. In a masterful summary, Dr. David McK. Ritchie integrates the previous contributions and discusses other aspects of the problem.

For those with special interest in psychic pharmacology, a few pleasurable and informative hours may be well spent by perusal of this symposium. The bibliography appended to each of the six major contributions references further sources on other phases of these subjects.

—ARTHUR J. LEVINS, Lt. Col. MC USA

## Monthly Message

Mr Clarence B Randall, Special Assistant to the President, has kindly granted me permission to quote the final paragraphs of his article, "The High Adventure," one of a series of lectures which he gave at harvard University during the past year

Today the young man must see his job against the background of mankind's struggle for survival. A new destiny awaits him from which there is no escape

"From this very gravity of our problems is sure to come a new earnestness of purpose and a new understanding of the significance of education itself

•

"The ultimate test of any intellectual discipline however is not what it does for others but what it achieves within the life of the particular individual. The cultivation of the mind and the illumination of the spirit are ends in themselves and bring their own rewards. Education is too precious a thing to be measured by a money index. Obviously it is important that each of us know how to make a living but that is not the ultimate purpose of life itself. Far more important than the making of a living is the living of the life and the highest aim of all education must be to make life richer and fuller. As the man grows within himself his company gains and society gains but it is the inner growth which must be the end sought

"Today the challenges are far greater far more exciting. Young men with vision will see this and will accept the new responsibilities with eagerness and without fear

The rewards for living worthily transcend anything that human history has known. They will go to those who by cultivation of the mind and illumination of the spirit reach the highest level of inner growth."

## Foreword

The *United States Armed Forces Medical Journal* is the medium for disseminating information of administrative and professional interest to all medical personnel of the Department of Defense. The Assistant Secretary of Defense (Health and Medical) and the Surgeons General of the several services invite all medical officers, dental officers, Medical Service Corps officers, Nurse Corps officers, and officers of the Veterinary Corps of the Armed Forces, and the medical consultants of the Army, Navy, and Air Force to submit manuscripts for publication in this journal.

## THE TREATMENT OF RHEUMATIC CARDITIS WITH CORTISONE

HORACE C. GIBSON *Colonel MC USA (Ret)*

**D**URING the past few years, there have been several important advances in our knowledge of rheumatic fever. The most significant of these were (1) the accumulation of data incriminating beta hemolytic streptococci in the initiation of the train of events in rheumatic fever,<sup>1-3</sup> (2) the prevention of rheumatic fever by prompt penicillin therapy of hemolytic streptococcal respiratory infections,<sup>1,3,4</sup> (3) continuous penicillin prophylaxis in the rheumatic individual,<sup>1,4,5</sup> and (4) hormone suppression of the inflammatory process during the period of activity.<sup>1,4-6</sup>

The controversy that has been carried on in the medical literature for over six years concerning the usefulness of hormone therapy in rheumatic fever is largely due to inadequate reporting of detailed clinical data, particularly regarding the severity of the symptoms, the duration of the disease prior to beginning treatment, the adequacy of the dosage, and the duration of treatment throughout the entire period of clinical evidence of activity. It is believed that with detailed tabulation of cases, readers have a better chance of evaluating the method of treatment and the results. This article evaluates the treatment of active rheumatic carditis by prolonged bed rest, chemotherapeutic drugs, and hormones. Thirty eight cases are presented—12 in graphic form (figs 1-15), 15 individually, and 11 in summary (table 1). Only 3 of the patients were children, the rest were adults—3 dependents, 2 WACs, and 30 soldiers.

## Additional Remarks, Final Examination, and Disposition

*Case 13* This patient a housewife was admitted to the hospital four times (total hospitalization 6 months) and also was treated as an outpatient. She received digitalis until 21 April 1954. Activity was not suppressed until August. Follow up on 15 November 1954 showed grade II aortic insufficiency and stenosis mitral insufficiency and blood pressure of 140/20 mm Hg. These were compensated and asymptomatic.

*Case 14* Throat cultures were positive 10, 16 September and 7, 24, 27 November and 5 December but negative thereafter. Carditis was active for 6 months. Chorea persisted until May 1954 (9 months). After May and at the time of the patient's discharge to duty 14 July 1954 the clinical findings were negative except for a grade II apical systolic murmur. The patient's weight had increased from 122 to 138 pounds.

*Case 15* This patient was treated with from 5.3 to 8 grams of salicylate daily for 5½ weeks with persistence of joint pains, heart murmurs, erythema marginatum and lowest sedimentation rate 19 mm. All findings except the heart murmurs subsided on cortisone therapy. The apical murmur gradually became a faint grade I systolic. The basal murmur remained grade II. Hospitalization was prolonged for convalescence, considerable dental work and a tonsillectomy. The patient was returned to duty with a P 3 profile on 6 January 1955.

*Case 16* Electrocardiographic changes with wandering pacemaker and a systolic murmur were demonstrated during the first three weeks of aspirin therapy. After cortisone therapy the electrocardiograms were normal, no murmur could be heard and the patient's weight increased from 60 to 90 pounds. The child returned to school September 1954. On the last examination 14 April 1955 clinical findings were negative and the child weighed 88 pounds.

*Case 17* This patient developed an apical diastolic murmur in 10 days while receiving 8 grams of aspirin daily but the murmur was not heard on 1 May or thereafter. By late September only a grade I systolic murmur was present at the base and apex. After rehabilitation the patient was discharged to duty 7 January 1955 on prophylactic penicillin.

*Case 18* This patient was discharged to duty 17 August 1954. At that time his heart size was normal, a grade I mitral insufficiency murmur could be heard after exercise, the P-R interval was 0.14 second and the patient's weight had increased from 132 to 158 pounds.

*Case 19* When this patient was returned to duty 30 August 1954 his heart was normal, the P-R interval was 0.16 second, he was asymptomatic and his weight had increased from 140 to 164 pounds.

*Case 20* The patient had a low grade fever for 6 weeks. He was returned to duty 3 November 1954 symptom free except for a grade I systolic murmur. Physical examination <sup>normal</sup> <sub>electrocardiogram</sub> antistreptolysin "O" titer C reactive protein <sub>normal</sub>.

fluoroscopic examination were negative on 14 March and 8 September 1955. No murmur was heard and the patient's weight had increased from 146 to 155 pounds.

*Case 21* The patient was returned to duty 8 September 1954. His heart was negative; no murmur could be heard; the P-R interval was 0.16; the rate was 74; and the patient was asymptomatic. On follow-up examination 7 January 1956 there had been no recurrence—no murmur could be heard and the electrocardiographic, roentgenographic and physical and laboratory examination findings were all within normal limits. The patient had gained 10 pounds in weight.

*Case 22* This patient, a housewife, spent  $4\frac{1}{2}$  months in the hospital. Evidence of activity persisted until 15 January 1955. The murmurs were the same on 8 March 1955.

*Case 23* Electrocardiographic findings in this patient were normal and the P-R interval was 0.12. No murmur could be heard on the last examination, 14 October 1955.

*Case 24* The cortisone dosage for this patient was inadequate the first 4 months of his hospitalization. An apical systolic murmur became prominent and an apical diastolic murmur was heard intermittently through August 1955. Electrocardiographic findings were positive through September. The patient received cortisone therapy for  $8\frac{1}{2}$  months. Convalescence was uneventful through 45 days of physical reconditioning and the patient was discharged to duty 21 November 1955 with no restrictions. The last follow-up examination, 17 January 1956, showed recurrent slight stiffness in the right hip on strenuous exertion. The patient's pulse was 76; blood pressure 120/70 mm Hg; and a grade I-II systolic murmur was heard at the apex and base but no diastolic murmur was heard. The patient's weight had increased from 170 to 206 pounds.

*Case 25* This patient probably had an intercurrent infection in May for which he was adequately treated. No murmur was heard on repeated examinations after 20 May and the electrocardiographic findings remained normal. The patient was asymptomatic and all findings were within normal limits at his discharge to full duty, 17 October 1955.

*Case 26* This patient was asymptomatic after the first week of hospitalization and the systolic murmur was no longer heard after mid May. Convalescence and rehabilitation were uneventful and the patient was returned to full duty 21 October 1955 with all findings within normal limits. His weight had increased from 160 to 190 pounds.

*Case 27* This patient's course in the hospital was uneventful throughout his treatment. Systolic murmurs persisted through September. No murmurs were heard after mid October. He gained 10 pounds in weight. Examination was negative on his discharge to full duty, 10 November 1955. Penicillin by mouth was continued.

I have used cortisone since 1951 to relieve symptoms and suppress the inflammation of rheumatic fever, and the patients treated in 1951 were reported previously.<sup>4</sup> The first 12 patients reported herein were treated in a U S Army hospital in Japan—2 in the fall of 1952 and 10 during 1953. Some were admitted directly to the hospital and some were transferred from Korea or other medical installations where they had been on supportive therapy for varying periods of time. The last 25 patients were treated at this hospital during the period 1954-1956.

These patients were started on cortisone as soon after admission as the diagnosis was made. An antibiotic—penicillin, unless the patient was known to be allergic to it—was started at the same time, and in some cases prior to arriving at a definite diagnosis. In addition, each patient was placed on strict bed rest until the acute symptoms subsided, after which bathroom privileges were allowed. Hemtoret and sedimentation rate, antistreptolysin "O" titer, throat culture, and electrocardiographic studies of each patient were reported twice weekly during the early stages of the illness and weekly thereafter. Heart fluoroscopy and roentgenograms were done early and one or more times later. Routinely, potassium chloride, 3 grams daily in divided doses, was administered orally. Serum potassium levels, which were determined frequently, remained in the normal range. Each patient was seen daily by the same physician. All patients were examined once or twice weekly by me, and were seen at various times by a consultant in cardiology. Temperature and pulse were checked by the ward nurse or ward master two to four times daily, and graphic charts were kept. The values shown in the graphs are the highest daily recordings. For the pulse rate, this admittedly is a poor method, nevertheless, it affords a fair figure for comparison, since the ward personnel taking the pulse rates were unaware of more than routine emphasis.

The initial dose of cortisone was 300 to 400 mg, depending on the weight of the patient. The oral route was preferred because of the ease of administration, the rapidity of absorption, and minimal discomfort to the patient. The daily dose was given initially at six-hour intervals and then at eight hour intervals after the acute symptoms had subsided. For two patients weighing over 200 pounds, it was necessary to increase the dose to 500 mg daily before a remission in the various signs of disease activity could be obtained (cases 10 and 24).

The early concept was that suppression of positive signs of activity by the use of hormone therapy should be maintained throughout the active period of the disease. This was found to be practicable in all except two cases (9 and 11) who were evacuated to the United States of the t

of their periods of service. Both had developed chronic corticoidism and both had proloaged periods of activity—seven and eight months at the time of evacuation. In general the initial daily dose was continued until the patient was asymptomatic and the sedimentation rate, C reactive protein, and electrocardiogram had returned to normal. This was usually from 7 to 10 days but in some cases longer. As a rule, the temperature and pulse rate were near normal at this time, although from the graphs presented it will be noted that minor elevations in the temperature (usually in the afternoon or evening) and frequent elevations in the pulse rate at bed rest were recorded throughout the period of activity.

An attempt was then made to reduce the daily dose by 50 mg at four to seven day intervals to a daily dose of 200 to 300 mg depending on the size and weight of the patient. Based on previous experience it was believed that approximately 1 mg of cortisone per pound of weight was the minimal dose that would maintain any appreciable suppression of disease activity. To obtain adequate suppression approximately 15 mg of cortisone per pound of weight was the dosage goal for the first six to eight weeks of therapy. However, in cases 4, 6, 7, 8, 11, 14, 18, and 24 when fever symptoms elevated sedimentation rate, gallop rhythms or prolongation of the P-R interval recurred, the dose was increased above this level. After six to eight weeks on relatively high doses of cortisone and provided all findings indicated possible cessation of activity, the hormone was again decreased. This was accomplished by reducing the daily dose by 25 or 50 mg at three or four-day intervals to zero or until signs of recurring activity were noted. In that event the dose was again increased until these signs reverted to normal, and then the increased dosage was continued for several weeks longer after which the tapering off process was again attempted.

In general the results of this plan of therapy have been most encouraging. The temptation to reduce the dosage of hormone prematurely is great especially among medical officers using this method of treatment for the first time. This tendency must be constantly discouraged for best results. Case 4 is an example. This patient required repeated courses of cortisone, but after six months was successfully carried through his period of activity without demonstrable heart damage. It should be noted that cortisone was started early in the disease in this patient, when evidence of cardiac damage was limited to precordial pain and first degree heart block. Cases 1, 2, 19, 20, 21 and 28, 38 were treated promptly and the periods of activity were short. Case 16 was a nine year old child treated for five months with no residual cardiac damage evident after 13 months follow up. The other two children also recovered with no residuals after one year's follow up in one and six months' follow up in the other. Cases

9, 17, and 21 were treated for four, seven, and nine and a half months respectively, with recovery from apical diastolic murmurs that were heard frequently but later could not be heard by several internists and a consultant in cardiology. After prolonged treatment, a total of 23 patients (60.3 per cent) were left with no demonstrable heart damage, although carditis was evident in all before treatment.

Whether any of these patients would have sustained cardiac valvular damage had they been treated with salicylates can, of course, not be answered. In this series of patients, 33 of the 38 had significant murmurs. These disappeared in 19 patients (cases 9, 16, 17, 19, 21, 24-27, and 28-36) or 57.6 per cent (table 2). The importance of early diagnosis and initiation of hormone therapy is borne out by the finding that murmurs disappeared in 78.6 per cent of those starting treatment within the first week of hospitalization, as compared with 42.1 per cent of those starting treatment in the second week or later. The P-R interval was prolonged in 11 patients; it returned to normal and remained normal in all but one (case 12). Due to difficulty in diagnosis and reluctance on the part of the ward officer to use adequate suppressive doses sufficiently long, this patient was inadequately treated.

TABLE 2 Frequency of disappearance of murmurs at end of therapy

Interval between admission to hospital and beginning of therapy (days)	Patients with significant murmurs	Disappearance of murmurs	
		Number	Per cent
1 to 7	14	11	78.6
8 to 14	10	4	40.0
14 and over	9	4	44.4
Total	33	19	

Undesirable effects of hormone therapy were not too pronounced in this series of patients. Occasionally, indigestion was treated with antacids. Most to be feared is intercurrent infection. Only upper respiratory infections were encountered. The hypercortical features disappear a month or so after treatment is discontinued. Occasionally, purple striae appear and remain. The occasional elevation in blood pressure returns to normal within three or four weeks. The increase in appetite is remarkable and accounts for frequent gains in weight, requiring dietary restrictions. No instance of anemia persisting on hormone therapy was found.

#### DISCUSSION

To those of us who treat rheumatic fever and observe its sequelae, the knowledge of our limitations is still urgent

Physicians in the past have been keenly aware that, despite their greatest efforts success or failure in preventing death or cardiac disability was due in large part to whether there was (1) inflammatory involvement of the heart valves, (2) continued inflammatory activity in the myocardium, with resulting heart enlargement and failure, (3) inflammatory involvement of the neuromuscular tissue with varying degrees of heart block, occasional paroxysmal nodular tachycardia or auricular fibrillation, (4) prolonged duration of the attack with recurrences and continued activity or (5) no recurrence and no further activity. The prevention of the initial attack at present depends on the timely diagnosis and treatment of streptococcal infection in the susceptible individual. Prevention of future attacks in a known rheumatic individual is now considered possible. Successful immunization appears to be a hope of the future.

An understanding of the peculiar biochemical relationships between the beta hemolytic streptococcus and the rheumatic individual is still lacking. The concept of the immuno-allergic pathogenesis of rheumatic fever was recently enhanced by the work of Jellors and Ortega.<sup>4</sup> Their work, although specifically concerned with glomerulonephritis, disclosed a feature common to most collagen diseases, namely, the localization of gamma globulin at the site of the lesions. It is assumed that the gamma globulin serves, at least in part, as antibody against antigen that has localized at the site of the lesions. Since so much work has established the streptococcus as the producer of the antigenic substances, the old concept of auto-antibodies acting solely against an intrinsic tissue antigen can be discarded.

In patients with active disease and in those who have recovered from rheumatic fever, the importance of penicillin in preventing hemolytic streptococcal infections has been established without question. A regular prophylactic regimen or, as a lesser choice, the widespread prophylactic treatment of upper respiratory tract infections in known rheumatic fever patients with antibiotics or sulfonamides will doubtless prevent more valvular heart disease than the use of any form of therapy available for the acute attack.

Prior to 1952, acute rheumatic fever was treated with an initial short course of an antibiotic, usually penicillin. It has since been shown that penicillin or another suitable chemotherapeutic drug should be given initially in high dosage for 10 days to ensure the eradication of smoldering streptococcal infection.<sup>1, 10</sup> Treatment should then be continued in prophylactic dosage. In 1953 the American Rheumatism Association recommended that this prophylactic treatment be continued in all rheumatic children to the age of 18 years or for 5 years after an attack of rheumatic fever if this period overlaps or the attack occurs after the age

of eighteen.<sup>4</sup> Early in 1955 this recommendation was changed to lifetime administration of prophylactic penicillin.<sup>10</sup>

It has been my impression that physicians in general have been slow to put into operation this plan of specific prophylaxis. This hesitancy is probably due to the continuing campaign against the indiscriminate use of antibiotics and the many reports of complications of antibiotic therapy. Second in importance to the prevention of future attacks of rheumatic fever and their consequent cardiac damage is the possible prevention of subacute bacterial endocarditis. According to a recent report by Wallach, Lulash, and Angrist<sup>11</sup> dealing with children under 10 years of age dying of rheumatic heart disease, rheumatic activity is responsible for death in 92 per cent and heart failure resulting from mechanical impairment in 8 per cent. From age 10 through age 19, rheumatic activity causes 52 per cent of deaths, heart failure 12 per cent, and bacterial endocarditis 36 per cent. In later decades, rheumatic activity becomes progressively less important and heart failure more frequent as the cause of death. Bacterial endocarditis is of greater importance during the second through the fifth decades, being responsible for death in 36 per cent, 47 per cent, 39 per cent, and 29 per cent, respectively.

*Streptococcus viridans* is frequently cultured from the throats of patients on penicillin prophylaxis. Whether the blood level maintained by oral doses of penicillin or monthly injections of benzathine penicillin G is sufficient to prevent these organisms from becoming implanted in the heart valves has not been determined. This is analogous to the concept of prevention of beta hemolytic streptococcal infection. We occasionally culture these organisms from the throats of patients on prophylactic therapy, especially patients in the hospital wards who are receiving cortisone. However, the organisms do not establish a sustained infection with usual clinical manifestations and subsequent elevation of the antistreptococcal "O" titer.

It is well known that more intensive treatment is usually required to eradicate an established infection caused by either *S. viridans* or beta hemolytic streptococcus. The regimen of choice for prophylaxis is 169.3 mg (250,000 units) of potassium penicillin G on an empty stomach, 30 minutes before breakfast and at bedtime. After the patient leaves the hospital, the dosage may safely be reduced to 169.3 mg (250,000 units) once daily. Since the advent of long acting benzathine penicillin G, better control in many instances can be maintained by monthly injections of 990.9 mg (1,200,000 units). This is especially advantageous in hospitalized patients. While the patient is hospitalized, bi-monthly injections are preferred because of the increased likelihood of contact with carriers of streptococci. If the patient is sensitive to penicillin, 1 gram of sulfadiazine each may be used.

The really important question about the hormones in rheumatic fever is whether or not they will prevent valvular heart disease and other long term sequelae. We can reasonably conclude after many years of use that salicylates do not prevent a crippled heart. Salicylates do ameliorate the disease but even when used early in the acute attack valvular disease may still develop. It appears that the main difficulties with hormone therapy have been (1) the tendency to study or observe the patient too long before starting therapy (2) a hesitancy to use fully suppressive dosage and (3) the ever present tendency to discontinue treatment too early or to treat in "courses." There are good explanations for these failures. These include lack of sufficient data on which to make an early diagnosis, the fear of aggravating congestive failure and the reluctance to changing a patient into a pugy, acne spotted caricature of his former self. The difficulty in diagnosis of the atypical case cannot be overcome with present knowledge and laboratory help. Chief reliance is on experience, training and an acute awareness of rheumatic fever in the differential diagnosis.

In the severely ill patient especially in the first two decades of life steroids may often be lifesaving. In general hormones do not aggravate congestive failure for more than 24 hours or so. If improvement does not occur after 48 hours of treatment it usually means that the dosage is too small. However, if after the disease is controlled for a few days or a week or so the hormones are discontinued or reduced to ineffective levels, there is usually a prompt recurrence, often more severe than initially. This error in treatment of rheumatic carditis is frequent and grave. It leaves the suppressed adrenal glands unable to react at maximum capacity. Occasionally rapid deterioration and death ensue. These deaths are sometimes reported as treatment failures.<sup>12</sup> A low sodium diet, mercurial diuretics, digitalis, oxygen et cetera often are necessary in such patients during the early phase of therapy. Massell,<sup>6</sup> in reviewing 10 reports of patients with rheumatic carditis treated with hormones, found definite improvement of congestive failure in 75 per cent.

Since corticotropin (ACTH) and cortisone cause a retention of sodium and water the rapid clearing of signs of congestive failure in my experience is good evidence that the inflammatory process in the myocardium is controlled. Further evidence is the control of gallop rhythm and tachycardia (cases 10 and 12) although the latter often is incompletely controlled until the period of activity is over. Although the patient may be on a seemingly suppressive dosage in many instances throughout the period of activity turning him in bed or having him sit up is sufficient to produce an abnormal increase in pulse rate. Pericarditis usually clears in a few days as manifested by disappearance of a friction rub. Electrocardiographic changes may take longer.

especially S T segment elevations and T-wave changes. Some of these T wave changes are considered to be due to serum potassium fluctuation. The P R interval, unless it is a fixed prolongation from previous cardiacs, has returned promptly to normal, in my experience. In some patients the disease cannot be adequately suppressed even with maximum doses of cortisone. However, with this type of patient, it is my belief that it is even more important to continue the cortisone, even though it only partially suppresses the disease. This may prevent severe damage and possibly a fatal outcome during a fulminating course.

The main question of preventing chronic valvular heart disease has not been settled yet. Authors appear to be reluctant to give an opinion on this. One reason for this reluctance is the fact that most patients with recurrent attacks already have valvular damage when seen. New patients often have murmurs when first seen, or develop murmurs prior to starting treatment or prior to being given a definite diagnosis of rheumatic fever. The changing character of murmurs in acute rheumatic endocarditis is well known. However, after carefully observing and treating patients for the past six years with this question in mind, I am convinced that the progression of valvular damage ceases with the suppression of inflammation by adequate hormone therapy. In general, existing murmurs remain the same or become less pronounced during adequate treatment. On adequate suppressive therapy throughout the period of activity, murmurs, both systolic and diastolic, frequently disappear permanently. If no murmur is present prior to treatment, the patient does not develop one except occasionally in fulminating cases during the first few days before suppressive therapy is effective.

The recent work of Roy and Massell<sup>13</sup> showed disappearance of significant murmurs in 40 per cent of 66 patients. Disappearance of murmurs was twice as common in 47 rheumatic children treated with large doses of cortisone (150 mg daily for an average of 14 weeks) as in a comparable group of 41 children treated with smaller doses (100 mg daily for an average of six weeks). Coste and Oury,<sup>14</sup> in a report of 43 cases, did not see signs of carditis after 48 hours' treatment, if patients were started on hormone therapy before signs of carditis appeared or were started on such therapy in the early stages of carditis. Apparent exceptions to the above will be seen, but if a search is made one will find either inadequate treatment in dosage or duration of hormone therapy, or the likelihood of recurrence of a streptococcal infection in a patient not protected by prophylactic therapy.

The impression gained from clinical observation is that hormone therapy does not shorten the duration of the disease. It is not intended to imply that short treatment is reasonable to expect that the

pronounced in the early acute febrile stage. The proliferation of the valvular endocardial and subendocardial cells, often in palisade arrangements with swelling of the interstitial connective tissue and a dense leukocytic infiltration, occurs early during the exudative and proliferative phases of the disease. If this process can be prevented or interrupted in its initial stage, the thickening, fusion and retraction of valve leaflets that occur repeatedly with each new episode of rheumatic fever can be curtailed. The extent of curtailment depends on variables such as the severity of the process in a particular patient and the adequacy of the hormone dosage administered. The same can be said for the involvement of the myocardium.

The characteristic Aschoff's body is the inflammatory lesion incriminated by pathologists to account for acute dilatation and heart failure. Furthermore, congestive heart failure occurring in the course of chronic valvular heart disease is now considered to be due to reactivation or continued activity of myocarditis. Murphy<sup>45</sup> has demonstrated that these Aschoff's bodies develop in and from injured myofibers that are being necrotized. The intimal and medial changes in small arteries supplying the auriculoventricular conductive tissue as well as the edema and infiltration with polymorphonuclear cells, lymphocytes and plasma cells of this tissue probably account for the irregularities and heart block that appear temporarily. Whether this is true or whether the Aschoff's body is responsible remains to be established. The Aschoff's body is peculiar to the myocardium and does not appear in the inflammatory valvulitis, endocarditis, or pericarditis of rheumatic fever.

Finally, it is necessary to adopt a concept of management of rheumatic fever similar in many ways to that of tuberculosis. This is especially true in the Armed Forces. The military patient must be hospitalized throughout his illness and convalescence. Children and other dependents need hospital care for relatively short periods when hormone suppression is used. After the acute symptoms and signs in the rheumatic child are normal, strict bed rest is neither practical nor desirable. Supervision by a parent at home with weekly office visits has proved a most satisfactory practice.

#### SUMMARY

The results of treatment with cortisone of 38 patients with acute rheumatic carditis are reported. Treatment was continued in sufficient dosage to suppress the rheumatic activity throughout the period of immuno-allergic reaction in all but two patients.

Twenty-three of the 38 patients (60.5 per cent) were left with no evidence of heart damage. Thirty-three patients had significant murmurs. In 19 (57.8 per cent) these disappeared during treatment and remained absent throughout the follow-up period.

All patients were treated with chemotherapeutic drugs in therapeutic dosage early, and in prophylactic dosage thereafter. No recurrences of rheumatic fever were apparent.

# A NEW OVERHEAD ANESTHETIC PANEL FOR PIPED GASES, VACUUM, AND ELECTRIC OUTLETS

JAMES B BUTLER *Captain MC USN*

FRANK MOYA *Lieutenant MC USNR*

JOHN S. LUNDY *M. D.*

**I**N THE PAST three decades great strides have been made in the field of anesthesiology. One of these advances was the introduction at the University of Wisconsin of the first central gas piping system.<sup>1</sup> Since that time the practice of central piping spread to other hospitals throughout the country and the techniques and equipment have been perfected so that today there is a high degree of safety, efficiency, and economy. One problem that still remains in the operating room area, however, is the handling of the high pressure rubber tubing connecting the gas machine to the outlet.

Several attempts have been made to overcome this problem by the use of wells or "islands" beneath the table, suspension from the ceiling or wall by means of arms or overhead cranes, and suspension poles that extend from the floor to the ceiling. These all have the disadvantage of being cumbersome and usually still leave the tubing hanging at dangerously low levels.

Another problem in the modern operating room is that of the steadily increasing need for more electric connections. This stems from the anesthesiologist's greater utilization of electronic instruments in helping him keep track of the patient's condition. In addition to these monitoring devices the advent of intra-cardiac surgery with pump oxygenators requires even more electric outlets conveniently placed. This introduces the hazard of electric cords strewn about the operating room where they can be stepped on, worn, frayed, or unplugged by people walking about.

In planning the operating rooms of the new U. S. Naval Hospital at Great Lakes III, it was decided after much consideration and consultation that the use of a fixed overhead panel

---

From U. S. Naval Hospital at Great Lakes III and Navy Foundation, Rochester, Minn.

for piped gases, vacuum, and electric outlet would most likely solve the above problems.

As shown in figure 1, the panel consists of a stainless steel housing about 28 inches long and 9 inches wide, fastened directly to the ceiling construction over and behind the position of the gas machine. At the lower end of the panel are outlets for oxygen, nitrous oxide, and vacuum. The lines are connected to their respective hoses with noninterchangeable connectors. At each end of the panel there is a duplex, explosion-proof electric outlet.

Figure 1 Overhead utility

There is a stainless steel panel about 28 inches from the bottom of the chair which can be suspended or it can be fixed to the wall.

The lowest part of the panel, this being a stainless steel panel, is enough to be hazardous rounded at the bottom.

We have briefly described the overhead utility panel for piped gases,

and it will be a great help to the dentist during an emergency. The panel is fastened to the ceiling with a rubber band.

# EFFECT OF PROCLORPERAZINE ON PSYCHOLOGIC, PSYCHOMOTOR, AND MUSCULAR PERFORMANCE

FRED B BENJAMIN D M D Ph D

KIMIO IKAI, M D

HENRY F CLARK B A

**D**URING recent years, tranquilizing agents have gained great prominence in clinical practice. As Brucke<sup>1</sup> pointed out, however, these drugs possess an almost infinite number of properties. This raises the problem of the nature of various effects produced and their relation to the tranquilizing effect. The investigation herein reported approached this problem by using one drug and one dose level in a great variety of tests.

## MATERIALS AND METHODS

The drug used was Compazine (brand of prochlorperazine) which is an analog of chlorpromazine. The dose was 10 mg. This produces a marked tranquilizing effect without interfering with the normal daily activities of the subject. The only side effect that might be expected is a slight somnolence. In order to differentiate between the true tranquilizing effect of the drug and this side effect, one control group was given not a pure placebo, but 10 mg of phenobarbital. A second control group received no drug.

The experiments were divided into three groups: (1) 10 mg of prochlorperazine was given by mouth one hour before the start of the experiment, (2) 10 mg of phenobarbital was given by mouth one hour before the start of the experiment, (3) no medication was given. The drugs were supplied under code number, so that neither the subject nor the experimenter knew which drug was being tested.

Fifteen men, 20 to 43 years of age and with no known clinical disturbances, were chosen as subjects. Six of these subjects served for two series of experiments. Each subject was tested under the three experimental conditions, and for each

---

From University of Pennsylvania School of Medicine, Philadelphia, Pa., and the Aviation Medical Acceleration Laboratory, U. S. Naval Air Development Center, Johnsville, Pa.

tical evaluation each subject served as his own control. In order to eliminate as far as possible any effect of environmental conditions such as room temperature, noise level, and time of day, three subjects were always tested simultaneously, one under each of the three possible experimental conditions.

The following tests were used as an indication of psychologic, psychomotor, and muscular performance.

#### **Mental Performance**

*Memory of numbers.* Numbers were given, increasing from four to nine digits, and the subject had to write them down after a short interval. This test was analyzed as to the maximum span achieved and the total number of mistakes.

*Crossing "E."* All E's on a page of printed material had to be crossed out. This test was analyzed for the number of lines attempted within the 3 minute test period and for the number of mistakes and omissions.

*Code substitution.* Three lines were given, and the fourth one had to be filled in. The first line consisted of the letters of the alphabet arranged in correct order. In the second line, numbers were given in random order corresponding to each letter of the first line. The third line gave an arbitrary combination of letters, and the corresponding numbers had to be filled in from the code given in the upper two lines.

#### **Time Perception**

*Free time estimate.* The subject had to estimate an interval of one minute and the actual time was recorded.

*Tapping.* The subject was asked to tap out 60 seconds on a Veeder Root counter, and the actual time was recorded.

#### **Reaction Time**

*Simple reaction time.* A 360-millisecond time clock was arranged with two interruption switches. The operator started the clock with a click. The subject when hearing the click, had to stop it as soon as possible by pressing his switch.

*Choice reaction time.* The same arrangement as in simple reaction time was used, however this time the subject was told to respond only to one of two sounds of slightly different frequencies. The reaction time and the number of false responses were recorded.

#### **Reflex Activity**

Patellar reflex was determined by having a percussion hammer suspended in such a manner that on release it hit the tendon with controlled force. The movement of the leg was registered

by fixing a string to the heel. This movement was converted into vertical deflection and the amplitude was recorded on a kymograph.

### Pain Threshold

The volar side of the forearm was painted with India ink to assure maximum heat absorption. Initial skin temperature was determined with a radiometer. The arm was then exposed to a known amount of radiant heat ( $200 \text{ mW/sec/cm}^2$ ) and the time was recorded when the subject reported the first pricking pain.<sup>2</sup> The final skin temperature was then calculated from Buettner's<sup>3</sup> formula.

### Hearing Impairment

Hearing loss was determined with a Maico audiometer for 250, 1,000, and 6,000 cycles per second. The three values for hearing loss were combined to give one value for hearing impairment.<sup>4</sup>

### Muscular Co-ordination

**Punchboard** A plastic board had three holes arranged as a unilateral triangle with a side length of 4 inches. A metal stylus fitted the holes and a shoulder stopped the punch at a depth of  $3/16$  inch. The subject was asked to punch the three holes in sequence as rapidly as possible. The number of punches for a 3 minute period were counted.

**Rotary pursuit device** The subject had to follow with a stylus an irregular line on a rotating kymograph. The mistakes were automatically recorded on an Esterline Angus armeter. Any aberration caused a deflection, and the time of aberration determined the amplitude of the deflection. The results were analyzed as to the number of mistakes and as to the product of the number of mistakes and magnitude of deviation read in the arbitrary line units of the recording instrument.

### Muscular Performance

The heart rate, respiratory rate, respiratory minute volume, and oxygen concentration of expired air were determined, after which the changes in these values were observed during a 10-minute period of exercise and during 4 minutes of recovery. An ergometer bicycle with a wheel circumference of 1.96 meters was used. The resistance was 4 pounds, and the rate of revolution was fixed with a metronome at 40 revolutions per minute. Heart rate was determined with an electrocardiograph. Respiratory measurements were made with a Hutchinson respirometer. For the oxygen analysis, a Beckman model D oxygen analyzer was used. Data were collected immediately before exercise, 3 minutes after the start of exercise, 8 minutes after the start of exercise, and 3 minutes after the end of exercise. All experiments

were analysed as an individual comparison, taking each subject as his own control

## RESULTS AND DISCUSSION

Results 1 to 6 in table 1 give data on tests primarily involving mental performance. The differences for any single test are not significant but if the number of mistakes for crossing "E" (result 4) are combined with those of the code substitution test (result 5), the difference between the prochlorperazine and no drug groups is significant ( $p=0.05$ ). Such a combination may be justified, as the two tests show a good correlation ( $r=0.65$ ), however, this change may not be specific inasmuch as the phenobarbital group shows the same trend.

Time perception (results 7 to 11) was not affected by either of the drugs and if simple reaction time and choice reaction time are considered separately there also is no significant change. If the two are combined ( $r=0.53$ ), however, there is a significant drug effect that appears to be specific to the prochlorperazine group.

The initial skin temperature was slightly higher in the group using prochlorperazine (result 12) but the difference is not significant. In view of the known vasodilator action of such drugs,<sup>11</sup> however, this difference might be significant with a higher dose. There was no change in the pain threshold (result 13) and no impairment of hearing (result 14). The amplitude of the patellar reflex (result 15) was decreased in the prochlorperazine group, whereas phenobarbital had no effect. In tests primarily involving muscular coordination (results 16 to 18) there was inhibition in the prochlorperazine group. The differences are not all significant but the trend is the same in all tests.

On the whole there appears to be very little effect in tests primarily involving mental function whereas those tests largely involving muscular activity show impairment. To further elucidate this point the effect of prochlorperazine on muscular exercise was determined. Table 2 shows that in the pre exercise period there was no significant difference between groups. During exercise the only changes were increase of pulse rate and oxygen consumption in the prochlorperazine group. The differences were slight, and they become significant only if the 3 and 8 minute periods are combined.

In the postexercise period there was a change in pulse rate and oxygen consumption in the same direction as during exercise however the differences were not significant. The increased heart rate and the increased oxygen consumption for the prochlorperazine group during exercise indicate a decreased efficiency of work performance as confirmed by calculated efficiency values. An inhibition of muscular efficiency also is sup-

ported by the fact that in 7 runs out of 24 the subjects taking prochlorperazine volunteered the information that they found the work tiring, while no similar reports were made in the other groups.

In the clinical use of chlorpromazine, one of the side effects is parkinsonism, which occurs in about 10 per cent of all patients under intensive treatment.<sup>7,8</sup> The present investigation indicates that there is inhibition of muscular performance even with very low doses of prochlorperazine, as shown by the increased reaction time, the decreased amplitude of the patellar reflex, the decreased performance in tests of muscular coordination, and the decreased efficiency in muscular exercise. Inasmuch as the patellar reflex is a spinal reflex, central depression would tend to increase the response. A decreased reflex activity might be an indication that the site of drug action is peripheral rather than central. The investigations of Courvoisier and associates<sup>9</sup> and Archer<sup>10</sup> support such an interpretation. Dasgupta and Werner<sup>11</sup> thought that there is muscular inhibition and that it is due to depression of the reticular formation, but their experimental findings do not contradict a peripheral drug action. Darberg and Houghs<sup>12</sup> did not find any change in the muscle action potential, but it is difficult to draw any conclusions from a negative experiment.

We must be careful not to generalize these findings, as only one of the tranquilizing agents was used in this investigation and we do not know whether other agents produce the same effects. Some of the effects probably would be more clearly revealed if various dose levels of the drug were used; however, a dose sufficiently high to give a dose response curve might interfere with the daily activities of the subjects. Finally, we do not know to what extent clinically disturbed patients would show the same reactions as the normal subjects used in these experiments.

### SUMMARY

The effect of 10 mg of Compazine (brand of prochlorperazine) was compared with that of 10 mg of phenobarbital and with that of no drugs, in a series of double blind tests, using 18 subjects. Tests of hearing and pain perception and tests primarily involving mental performance did not show any specific changes. Tests involving muscular coordination, however, showed a lower performance, and tests of muscular exercise showed a decreased efficiency.

### CORONARY DISEASE AND RACE

The death rates from coronary disease during the past 15 years have increased much faster among nonwhites than among white persons. Much of this may reflect the increasing exposure of the nonwhite population to modern medicine as a result of large scale migration from the rural South to northern cities."

# WEEVER STINGS AND THEIR MEDICAL MANAGEMENT

BRUCE F. HALSTEAD Lieutenant MC USNR

**M**LAIBERS of the piscine family Trachinidae, the weevers, probably are the most venomous of temperate zone marine fishes. Trachinids are largely confined to the eastern Atlantic and Mediterranean coasts. They are relatively small fishes, the largest of which *Trachinus draco*, is not known to exceed a total length of 18 inches.

Weevers are primarily inhabitants of flat, sandy, or muddy bays. During the spring and early summer, they migrate into shallow waters to spawn. Trachinids have the habit of burrowing in the soft sand or mud, with only their heads partially exposed, and darting out at their prey. Despite their sedentary habits, weevers can move with great rapidity and are said to be able to strike an object with their opercular stings with unerring accuracy. Because of their habit of concealment, aggressive attitude, and highly developed venom apparatus, they constitute a hazard of which shallow-water divers, fishermen, and swimmers should be aware. Weaver stings may be extremely painful and on occasion may cause death.

The four species of weevers and their distribution are as follows:

*Trachinus araneus* Cuvier (fig. 1), Portugal, Mediterranean Sea, southward along the Atlantic coast of North Africa.

*Trachinus draco* Linnaeus (fig. 2), Norway, British Isles, southward to Mediterranean Sea, and coasts of North Africa.

*Trachinus radiatus* Cuvier (fig. 3), Mediterranean Sea, southward along the west coast of Africa.

*Trachinus vipera* Cuvier (fig. 4), North Sea, southward along the coast of Europe, and Mediterranean Sea.

---

From U. S. Naval Medical School, National Naval Medical Center, Bethesda, Md.

This investigation was aided by a contract payment to the School of Tropical and Preventive Medicine, College of Medical Evangelists, Loma Linda, Calif., from the School of Aviation Medicine, USAF Randolph Air Force Base, Tex., and a grant from the U. S. Public Health Service.

 Figure 2 *Trachinus draco* Linnaeus Figure 3 *Trachinus radiatus* Cuvier  
 (Courtesy of Smithsonian Institution) Figure 4. *Trachinus vipera* Cuvier

Weevers have been given a great variety of vernacular names. Some of the more common ones are sandeel bill, sandeel fish, stingbull, mor wiber fawr, adder pike, black fin, stinister stang, stinger, spider, sea dragon (England), araneus, drece draeuneulus, tragiæ (Ancient Latin) fibersing, foersing, (Sweden) fjärsing, fjärsing, (Denmark), petermännchen, drachenfisch, schwertfisch, raiao (Germany), pietermann, pieterisch, zand meelna, stekelvisch, stokeltjo, pukkelt, pukkeling, pukkelpuikelsnr (Holland), vive, avive, arngann, iragan, iapourichin bois de roc, boudereux, toget, claquedit (France), arnna, escorpion (Spain), joh, zan, zanja, zanjea, dra-anja, taratn (Yugoslavin), drakniar (Greece) lomole, abo, and nbokor (Gold Coast).

The venom apparatus of weevers consists of five to seven dorsal spines, an opercular spine on each side of the head, and the associated venom glands (fig. 5). The glands of both the

Figure 5 Photograph of a lateral view of the opercular sting of *Trachinus vipera*. The integumentary sheath has been removed to reveal the underlying glands.

opercular and dorsal stings consist of masses of large, polygonal, variable sized, distended, light pink cells, filled with finely granular secretion (fig. 6). A detailed morphologic description of this venom apparatus is being published elsewhere.<sup>1</sup>

Wounds usually are received while wading with bare feet in sandy areas inhabited by weevers. Stings from *Trachinus draco*

the deep water species most commonly occur among fishermen in attempting to remove them from their nets. Because of the danger of stings from dead fishes, some of the towns in France have passed police regulations making it illegal to sell weevers without first cutting off their stings.

### CLINICAL CHARACTERISTICS OF STINGS

Weever wounds generally produce instantaneous pain, described as a burning, stabbing or crushing sensation that initially is confined to the area about the wound and then gradually radiates throughout the affected limb. The pain becomes progressively more severe until it attains an excruciating peak usually within 30 minutes or less. The severity of the pain is such that the victim frequently screams in agony, thrashes about wildly, and may lose consciousness. Bourienne<sup>2</sup> reported a case in which the pain was so violent that the individual finally amputated his finger thereby obtaining prompt relief. Evans<sup>3</sup> mentioned fishermen hammering their fingers with a tbole pin and others wrapping the wound with vinegar soaked paper and lighting the paper in a desperate effort to deaden the pain. In most reported instances morphine fails to give relief. If untreated the pain usually subsides within a period of 2 to 24 hours.

Tingling, followed by numbness, subsequently develop the area about the wound. This is soon followed by redness, heat, and swelling. The edema is progressive, and within a half hour or more the entire limb is involved. Movement of the affected part is greatly restricted. The swelling may continue for a period of 10 days or longer. These initial symptoms of pain and inflammation may be associated with or followed by headache, fever, chills, delirium, nausea, vomiting, syncope, sweating, cyanosis, joint aches, ankylosis, aphonia, torpidity, cardiac palpitation, bradycardia, pronounced psychotic depression, respiratory distress, clonic or tonic convulsions, and death. Primary shock is a usual complication that must be guarded against, and secondary infections commonly occur in improperly treated cases. Lymphangitis, lymphadenitis, pyogenesis, and necrosis and sloughing of the tissue about the wound are not infrequent. Gangrene may develop, necessitating amputation.

The recovery period is extremely variable. Depending on the individual, amount of venom injected, species of weever, season of the year, and possibly the locality, the period varies from a few days to several months. In 1885, Bottari<sup>3</sup> reported a case which was complicated by a severe secondary infection that resulted in atrophy of the index finger, peripheral neuritis, and ankylosis. More than three years later the patient still was unable to touch an object with the affected finger without severe pain. De Marco<sup>4</sup> presented an interesting case of a 15-year-old boy in whom a weever sting on one of his fingers appeared to have stimulated a generalized epileptiform attack, and concluded that the venom acts as a cortical sensory motor stimulant. Additional clinical reports have been written by Gressin,<sup>5</sup> Coutiere,<sup>6</sup> Plancha,<sup>7</sup> and Grunio.<sup>8</sup>

#### CASE REPORT

On 24 July 1955 a 31-year-old Austrian zoologist was skin-diving about 200 meters off the Port of St. Angelo Ischia Island near Naples, Italy, at a depth of about 6 meters in the vicinity of a sand bank. In diving to the bottom he observed an unusually large weever, believed to be *Trachinus vipera*, lying partially buried in the sand. The fish did not appear to be disturbed by the intrusion and permitted him to touch it. Then suddenly it moved through the sand in a snake-like fashion and quickly turned facing the diver with fins vibrating in a most aggressive manner. Before he was able to withdraw the weever darted at him and struck at him twice, the first time striking only his face mask and then his right jaw.

Initially the wound bled profusely but without pain. This soon was followed by a stinging sensation not unlike that of a bee sting and the bleeding ceased. The pain rapidly increased in intensity and

the deep water species, most commonly occur among fishermen in attempting to remove them from their nets. Because of the danger of stings from dead fishes some of the towns in France have passed police regulations making it illegal to sell weevers without first cutting off their stings.

#### CLINICAL CHARACTERISTICS OF STINGS

Weever wounds generally produce instantaneous pain described as a burning, stabbing or crushing sensation that initially is confined to the area about the wound and then gradually radiates throughout the affected limb. The pain becomes progressively more severe until it attains an excruciating peak, usually within 30 minutes or less. The severity of the pain is such that the victim frequently screams in agony, thrashes about wildly, and may lose consciousness. Bourienne<sup>2</sup> reported a case in which the pain was so violent that the individual finally amputated his finger thereby obtaining prompt relief. Evans<sup>3</sup> mentioned fishermen hammering their fingers with a thole pin and others wrapping the wound with vinegar soaked paper and lighting the paper in a desperate effort to deaden the pain. In most reported instances morphine fails to give relief. If untreated the pain usually subsides within a period of 2 to 24 hours.

phils and plasma cells, none. The lymphocytes showed no toxic stimulation. Specific gravity of the urine was 1.028 and urobilinogen was normal. There were no other findings of significance.

*Figure 7. Appearance of patient who had been stung by a weever believed to be *Trachinus vipera*. Note edematous areas and extravasation of blood into tissues.*

**Family History.** The patient had a brother who died at the age of 14 years supposedly of hemophilia and he himself had a number of hemorrhages as a boy for which he was treated with vitamin-K therapy. He had had no recent hemorrhages.

took the form of a severe neuralgic pain involving the head and upper part of the chest. It became so severe that movement in the water was increasingly difficult but the diver finally managed to reach shore.

After about 15 minutes respiration became difficult and effort was required in order to continue breathing. The respiratory distress was relieved after about 10 minutes. The victim then noted that his ability to observe people's actions and voices was somewhat dulled; their movement and speech seemed to be greatly retarded. The injured side of his face gradually became inflamed although the actual wound site was only pinpoint in size.

The pain became unbearably intense and radiated outward from the jaw to involve all of the head and most of the chest. The victim groaned with the extreme pain and requested that someone shoot him and put him out of his misery. Upon the arrival of a physician he was given an injection of meperidine hydrochloride (amount not stated), but without relief. Two hours later he was given morphine sulfate again without effect. This was repeated soon after without result.

In about five hours the patient developed a severe burning sensation affecting the entire skin area of his chest. The area about his head became progressively swollen, reaching its greatest proportions on the second day. The first day the skin on the upper part of his body took on an erythematous hue, gradually becoming cyanotic on the second day. There also developed during this same period a massive hematoma involving a large part of the face, greater part of the head, neck, and upper part of the chest. The swelling was sufficiently extensive to impair breathing and swallowing. Movement of his thoracic muscles became exceedingly painful.

On the fourth day the patient was transferred from Ischia Island to the International Hospital in Naples where he was examined by the Medical Director, Dr. Paul Burkhard, who kindly provided this case history. At the time of admission the patient complained of pains in the right cheek, neck, thorax, scapular region, and skin of the head. These areas were greatly edematous and firm, with evidence of extravasation of blood into the tissues (figs. 7 and 8). At this time the patient was suffering from severe dyspnea because of the massive edema about the throat but within a day or two after his arrival at the hospital he began to improve rapidly.

Upon entry to the hospital the patient's temperature varied between 99° and 101° F. with pulse rate between 99 per min and 100 per min. Blood pressure was 130/85 mm Hg, red blood cell count 3,820,000 per  $\mu$ l, hemoglobin 82 per cent, platelet count 240,000 per  $\mu$ l, white blood cell count 13,600 per  $\mu$ l, neutrophils 77 per cent, lymphocytes 11 per cent, monocytes 11 per cent, eosinophils 1 per cent, baso

phile and plasma cells, none. The lymphocytes showed no toxic granulation. Specific gravity of the urine was 1.028 and urobilinogen was normal. There were no other findings of significance.

*Figure 7 Appearance of patient who had been stung by a weever believed to be *Trachinus vipera*. Note edematous areas and extravasation of blood into tissues.*

**Family History.** The patient had a brother who died at the age of 14 years supposedly of hemophilia and he himself had a number of hemorrhages as a boy for which he was treated with vitamin-K therapy. He had had no recent hemorrhages.

Treatment was symptomatic. Oxygen was administered for two days during the period of respiratory embarrassment and cold moist compresses were applied to the areas of swelling. Various opiates were administered but were ineffective. Solutions of vitamins, calcium, and glucose were given intravenously during hospitalization.

## TREATMENT

There are no known specific antidotes for weever venom, and treatment is for the most part symptomatic. Effort should be directed toward alleviating pain, combating the effects of the venom, and preventing secondary infection. The pain results from the trauma produced by the fish spine, the venom, and the slime and other irritating foreign substances introduced into the wound.

Weever stings usually are of the puncture wound variety, and removal of the venom is difficult. If seen early, it is sometimes advisable to make a small incision across the wound and apply suction. Irrigation of the wound with cold salt water is helpful, but generally is not possible in weever stings.

There is a division of opinion as to the advisability and of efficacy of using a ligature in the treatment of fish stings. If used, it should be placed at once between the site of the sting and the body, but as near the wound as possible. The ligature should be released every few minutes in order to maintain adequate circulation.

Whether or not a ligature is used, the member should be soaked in hot water for 30 minutes to an hour. The water should be maintained at as high a temperature as the patient can tolerate and as can be used without injury. This treatment should be instituted as soon as possible. If the injury is to the face or hand, hot moist compresses should be employed. High temperatures attenuate the potency of the venom. The addition of magnesium sulfate or epsom salts to the water is believed to be useful.

Infiltration of the wound area with 0.5 to 2 per cent procaine hydrochloride has been tried with good results. If local measures prove unsatisfactory, intramuscular or intravenous meperidine hydrochloride generally will be efficacious. Incisions should be closed with dermal sutures and the injured area covered with an antiseptic and a sterile dressing.

Prompt institution of the recommended treatment usually eliminates the necessity for antibiotic therapy, but if edema has resulted to any extent, antibiotics may be desirable. A course of tetanus antitoxin is an advisable precautionary measure.

The primary shock that immediately follows the stinging generally responds to simple supportive measures. However, the secondary shock resulting from the action of the venom may require immediate and vigorous therapy. Treatment should be directed toward maintaining cardiovascular tone and the prevention of any further complications. Respiratory stimulants may be required. Some of the advice given by Russell<sup>10</sup> in his excellent

review on the treatment of sting ray stings probably is pertinent to the handling of injuries produced by weevers.

Stahnke<sup>11, 12</sup> recommended a treatment for venomous animal stings that differs considerably from the preceding. The treatment is known as the L. C. (ligature cryotherapy) method. Immediately after being stung and without making an incision, the victim places a ligature between the site of the sting and the body at the point nearest the entrance of the venom. The hand or foot, including the ligature, is immersed in iced water. The ligature is removed after the member has been in iced water for not less than 5 or more than 10 minutes, but the affected part must remain in the iced water for a minimum of 2 hours. There is said to be no danger of frostbite if ice water alone is used. Salt must not be added. Stahnke stated that this method has been employed several times in cases of sting ray stings, with good results. There are no known instances in which it has been employed for weever stings.

### TOXICOLOGY

Winkler<sup>13</sup>, Schmidt<sup>14</sup>, Gressin<sup>15</sup>, Coutiero<sup>16</sup>, Pohl<sup>17</sup> and Phisalix<sup>18</sup> tested crude extracts of weever venom on various laboratory animals, but their studies were of a general nature and revealed little of the pharmacologic properties of the venom. Briot<sup>17-21</sup> and Evans<sup>22-24</sup> have shown weever venom to possess antigenic properties and to have a hemolytic effect on mammalian red blood cells. De Marco<sup>25, 26</sup> reported that weever venom injected into the dorsal lymph sac of frogs results in reflex excitability, tonic and clonic convulsions, paralysis, loss of position and spinal reflexes and death. Nothing is known of the chemistry of weever venom.

### SUMMARY

Weevers probably are the most venomous of temperate zone marine fishes. Because of their habit of concealment, aggressive attitude and virulent venom apparatus, they constitute a hazard to divers, swimmers and fishermen. The four known species, *Trachinus araneus*, *Trachinus draco*, *Trachinus radiatus* and *Trachinus vipera*, are largely confined to the eastern Atlantic and Mediterranean coasts. The venom apparatus consists of dorsal and opercular stings. Wounds produced by these fishes are extremely painful and may result in death. A recent case is discussed in detail. Treatment is largely symptomatic. There are no known specific antidotes. The pharmacologic and chemical properties of weever venom are largely unknown. Animal studies suggest that the venom contains both neurotoxic and hemotoxic fractions. Additional research on the subject is needed.

**T**HE PHYSICAL properties of Ivalon (polyvinyl formal sponge) are such that this material appears to offer many advantages not available with other synthetic materials for use in replacement of vascular segments. Among these advantages are the ease of fabrication of straight or branched tubes, the consistency and texture of the finished product which facilitates handling, suturing and tailoring to the requirements of a given situation and the porosity of the substance which is compatible with tissue infiltration. Several workers have carried out investigations to adapt this material to vascular surgery,<sup>1-3</sup> and some of these reports have been encouraging.

This presentation is the result of the trial of Ivalon for replacing segments of abdominal and thoracic aorta in dogs.

## MATERIALS AND METHODS

**Types of Ivalon Sponge.** Four types were used: (1) Rubatex Ivalon, porous, in sheets 1/8 inch thick, Type F 451 V manufactured by Rubatex Division of Great American Industries, Inc., Bedford, Va.; (2) Rubatex Ivalon compact, in sheets 1/8 inch thick, Type R 401 V; (3) Clay Adams Ivalon surgical sponge—Formulation V in bricks obtained from Clay Adams Co., Inc., New York 10, N. Y.; and (4) Prosthex Ivalon surgical sponge in bricks obtained from the Rarer Chemical Company, Ltd., Surrey, England.

**Rubatex Ivalon.** Both the compact and porous material appeared to have satisfactory elasticity, softness, porosity, and strength and seemed physically excellent for the purpose intended but the manufacture of tubes proved to be difficult. Preparation by boiling 15 to 30 minutes did not result in adequate fusion or adhesion, and preparation by use of dry heat at higher tempera-

From Valley Forge Army Hospital, Phoenixville, Pa. The surgical portion of this work was done at the Thoracic and Cardiovascular Research Laboratory, Presbyterian Hospital, Philadelphia, Pa. Project No. 6-60-01-002 of the Research and Development Division, Office of the Surgeon General of the Army. Dr. D. V. Jones, Presbyterian Hospital, Philadelphia, Pa.

tures required excessive compression of the sponge in order to attain satisfactory fusion, thus losing porosity. These disadvantages were particularly noticeable with the compact material, but apply to the porous as well.

*Clay-Adams Ivalon Surgical Sponge* This material proved very satisfactory to work with. Boiling produced tubes with excellent initial strength. The major disadvantage was the nonuniform pore size of this product. Frequent large bubbles resulted in areas of weakness or leaks of the finished tube wall.

*Prosther Ivalon Surgical Sponge* This material is similar to the Clay-Adams product, but has the advantage of more uniform pore size.

*Molds* Glass, polished stainless steel, copper, and brass rods or tubes having parallel or tapered sides were used to mold the Ivalon tubes. No branched segments were constructed because this study did not involve the use of complex grafts. For straight tubes, either glass or stainless steel molds were highly satisfactory. In the later stages of the work, slightly tapered molds were used to achieve a closer approximation to the size of the host vessel at both ends of the graft.

*Animals* Mongrel dogs ranging from 10 to 20 kg in weight were used. All animals were inoculated against distemper and hepatitis, and dewormed preoperatively. Anesthesia was produced with intravenous pentobarbital sodium, 15 to 30 mg per kg. Ventilation during surgery was achieved by connecting a Pneophore\* respirator to a metal endotracheal cannula and using 100 per cent oxygen. All animals were given 180 mg (300,000 units) of penicillin and 1 gram of streptomycin daily for the first 4 postoperative days.

*Surgical Technique* Abdominal aortic grafts were placed between the renal vessels and the trifurcation of the aorta. The grafted segment was covered with peritoneum routinely. Thoracic aortic grafts were placed in the mid descending aorta. Aortic occlusion was made possible either by hypothermia or by arterial shunting. The technique of anastomosis in all instances involved the use of a continuous over and over stitch after initial fixation with two or three everting mattress sutures. No 0000 or No 00000 Ethicon vascular sutures were used. The grafted segment was irrigated frequently with a dilute solution of heparin in saline. Vascular clamps of several types were used initially, and carefully sprung Glover ductus clamps\*\* were finally adopted for routine use, however all vascular clamps caused serious damage to

the vessel unless they were properly sprung and when properly sprung any were satisfactory

### EXPERIMENTS

**Group A Pilot Experiments** Six dogs were used in this phase of the work. Initially, the Rubatex Ivalon porous sponge was prepared by cutting 1 by  $\frac{1}{4}$  inch strips and wrapping them around glass or metal rods spirally, edge to edge. A counterspiral was then added as a second layer. Compression was obtained by loosely wrapping this preparation with 1 inch wide cotton tape. The tubes were then boiled for 20 minutes and stored in 1:1,000 Zephiran Chloride (brand of benzalkonium chloride) solution. This material was placed in the abdominal aorta in three dogs. All three animals died within 2 days. The material was too loosely fused, too porous, easily torn, and thicker than desirable. The tubes were patent in each case.

Rubatex Ivalon compact sponge was prepared in the same manner as above but with considerably more compression. The tubes were heated in a dry oven at 375°F for 15 to 20 minutes. These tubes were much stronger and thinner, but the porosity was very poor. Although the material was stiff, it sewed and handled well. These tubes were implanted in the abdominal aortas of two dogs. One of these animals died within 12 hours postoperatively of undetermined cause. The second dog was sacrificed 5 days postoperatively because he had developed paralysis of the hindquarters and had no femoral pulsations. The graft was completely occluded with clot. There was no fixation externally. The material was stiffer in the tissues than it had been at the time of implantation.

Rubatex Ivalon porous sponge, prepared as described below for Group B, Lot 1 was implanted in one dog. This material was strong and handled well. The graft was patent at 15 days and grossly appeared satisfactory.

All of these prostheses were 7 mm in internal diameter. One was 15 cm long, the rest were 5 to 6.3 cm in length.

**Group B Lot 1 Grafts** These prosthetics were made of 1 to 1 inch strips of Rubatex Ivalon porous sponge. The strips were wrapped on glass rods spirally, edge to edge, and a second layer was similarly wound in a counterspiral. The tubes were firmly compressed with an outer wrapping of cotton tape and molded by heating in a dry oven at 275°F. The grafts were stored in 1:1,000 Zephiran Chloride solution.

The prostheses were implanted in the abdominal aorta below the renal arteries in 10 dogs. Five of these animals died at 4, 7, 9, 13, and 26 days postoperatively. In three of these the cause of death was hemorrhage from the proximal aortic stump.

In one, thrombosis and hindquarter paralysis occurred. In the fifth, wound dehiscence caused the death. Three of these grafts were patent, one was partially clotted and one was completely clotted. The remaining five animals were sacrificed at 7, 9, 16, 46, and 81 days. The grafts were completely obliterated in all five animals.

Four of this group of grafts measured 9 mm in internal diameter, one was 7 mm. One graft was 7 1/2 cm long, and four were 2 to 3 1/2 cm long. The caliber in each instance was matched closely to that of the recipient vessel. The animals in which these grafts were implanted showed necrosis of the aortic stump between the site of occlusive clamping and the anastomosis. This had led to the hemorrhage in the three animals noted above. In grafts that were clotted, injury to the vessel was suspected of being the site of origin of the thrombus. There was no correlation between the caliber or length of the graft and the evidence of clotting. Microscopically, there was poor fixation externally, poor tissue infiltration in the interstices, and a moderate degree of inflammatory reaction about the grafts. The material handled well, was strong, and sutured well, but probably was too dense and somewhat too inelastic.

**Group C Lot 2 Grafts** A slight modification was introduced in the manufacture of this lot of grafts. The same material, Rubtex Ivalon porous sponge, was wrapped as in Lot 1, but was compressed less tightly. The grafts were molded by heating in a dry oven at 260° to 270°F and stored in 1,000 Zephiran Chloride solution.

Grafts of this type were implanted in two dogs in the abdominal aorta below the renal arteries. One animal with a 6 cm by 7 mm graft died at 13 days postoperatively with hindquarter paralysis caused by thrombosis. There was poor external fixation. The second animal was sacrificed 73 days postoperatively. The 3 cm by 7 mm graft was patent, had a good pseudointima, better but still incomplete infiltration, somewhat better fixation than with Lot 1, and a moderate degree of inflammatory reaction.

To determine the ideal degree of compression of the Ivalon sponge, the following experiments were carried out.

**Blocks of Clay Adams Ivalon** surgical sponge measuring approximately 1/4 by 1/2 by 2 1/2 inches were cut from the uncompresses bricks. These blocks were then placed in small aluminum presses, and compressed so that at one end of the strip the material was reduced to paper thickness and at the other there was no compression. These "wedges" were then implanted subcutaneously in several animals and left in place for periods of 1, 2, 3, 4, and 6 weeks. One half of these wedges had been stored in 1,000 Zephiran Chloride solution. The other half

were implanted immediately after boiling. One half of the Zephiran treated wedges were thoroughly washed in sterile distilled water before implantation. The others were simply wrung out and not washed.

The histologic observations on these implants are described below. The degree of compression best suited to vascular grafts was not found to be determined by tissue infiltration rate or quality but rather by the gross requirements of vascular grafts: that is, porosity compact enough to preclude troublesome oozing and thickness adequate for strength and for manipulation. The most satisfactory tubes were those prepared as in Lot 4 described below.

**Group D Lot 3 Grafts** These grafts were made from Clay Adams Ivalon surgical sponge. The bricks were thoroughly washed, frozen, and sliced in a meat slicer to  $1/8$  and  $3/16$  inch thicknesses. Strips  $1\frac{1}{4}$  inches wide were cut from these. The tubes were constructed of a double counterspiral as above, compressed to about one third of the total thickness, and boiled for 20 minutes in distilled water in an open pan. The grafts were then stored in Zephiran Chloride solution. These prostheses were very good from the standpoint of elasticity, strength, flexibility and porosity. There was no true fusion of the plastic, but the degree of adhesion made it difficult to separate the layers after boiling.

These grafts were implanted in the abdominal aorta in 15 dogs. Four of these animals died within 1 to 4 days. In two the cause of death was unexplained. One of these grafts was completely thrombosed in 3 days.

Eleven dogs were sacrificed 20 to 34 days postoperatively. In five, there was complete thrombosis. The grafts were  $2\frac{1}{2}$  to 4 cm long. In internal diameter, three were 6 mm and two were 7 mm. Thrombosis was not related to the site at which the aorta had been clamped. In six animals, the grafts were patent and lined by clean pseudointima. These grafts were  $2\frac{1}{2}$  to 6 cm in length, and from 6 to 7 mm in internal diameter.

This material handled well, was strong and elastic. It was not quite as porous as was thought desirable.

**Group E Lot 4 Grafts** These prostheses were made of the same material as lot 3.

After thorough washing the bricks were compressed to 50 per cent of their thickness in a press and boiled for 20 minutes. They were then sliced along the longer edge to a thickness of  $1/16$  inch. These strips were about 1 inch wide and  $8\frac{1}{2}$  inches long. They were wrapped spirally on glass rods overlapping one half the width and a second strip was counterwound. This gave a total wall thickness of four layers. This preparation

was then compressed to about one third of its original thickness and boiled for 20 minutes just prior to implantation.

The tubes were implanted in the abdominal aorta below the renal arteries in 14 dogs. Five of these animals died within 24 days. A specimen at 1 day and one at 24 days showed thrombosis. The other three were patent after 6 to 21 days.

Nine animals were sacrificed 32 to 360 days postoperatively. One of these implants was thrombosed after 43 days. This graft was 4.4 cm by 7 mm in size. One graft was partially thrombosed after 7 1/2 months; this graft was 3 cm in length. Seven grafts were patent. One of these was 4.6 cm by 6 mm, the others were 2.5 to 5 cm by 7 mm.

This material handled extremely well, held sutures nicely, was strong, and pulsed perhaps slightly more than the aorta. Grossly, the patent grafts were lined with a clean pseudointima layer. There was good external fixation. There was negligible inflammatory reaction.

**Group F, Lot 4 Grafts.** In this group, the prostheses, prepared as in Group L, were implanted in the descending thoracic aorta in 14 dogs. The animals were operated under hypothermia. Cooling was accomplished by immersion. Rectal temperatures of 73° to 88°F, with an average of 83°F, were attained. Aortic occlusion was carried out for periods of 20 to 50 minutes, with an average of 35 minutes.

Of these 14 dogs, one died the first day of cardiac arrest and nine died after 4 days from atelectasis with empyema. In one of these dogs, the implant was completely thrombosed 4 days postoperatively, while the others were patent and were lined by smooth fibrin, or were clean. One dog died after 26 days, in this case the graft showed a good pseudointima grossly.

The remaining three dogs were sacrificed 330 and 360 days postoperatively. The graft in one dog sacrificed after 360 days was partially thrombosed but not occluded. The other two, at 330 days, were patent and well lined by a smooth and glistening pseudointima 1 mm or more in thickness. There was good external fixation.

**Group G, Lot 4 Grafts.** These prostheses, which were prepared as in Group E, were implanted into the thoracic aorta in 19 dogs. Aortic occlusion was made possible by the use of a pump bypass. The left brachiocephalic artery and one femoral artery were cannulated. Tygon tubing from the proximal cannula was led through a Sigmamotor Pump and connected to the femoral cannula. The animal was given 1.5 mg of heparin per kg of body weight. After the implantation was completed, the bypass was taken down and the heparin neutralized with an equal dose of protamine sulfate.

This procedure made possible prolonged occlusion of the thoracic aortic in the normothermic dog. By adjusting blood flow through the pump, normal arterial mean pressure could be maintained both proximally and distally. The greatest difficulty in this technique arose from the necessity for using heparin which caused considerable oozing from the grafts and at the anastomoses.

Nine of the 19 dogs survived the procedure. One died in 2 days from bleeding and atelectasis. One died after a week from undetermined cause and one died after 10 days from hemorrhage, although the bleeding point could not be located. The causes of death in the 10 that died the first day were technical, relating to the difficulties of cannulation and control of bleeding after operation. The grafts in these animals were all patent, but all were specimens less than 24 hours old. The grafts in those animals which died in from 2 to 10 days also were patent.

Of the six dogs which were long term survivors, one died after 4 months following hemoptysis of unknown source. Five were sacrificed at 9 to 11 months postoperatively. Grossly, all these grafts appeared to be well lined with a smooth layer of pseudointima (fig. 1). There was good external fixation. These grafts were 3 to 6 cm in length and 10 mm in internal diameter.

Group H. Lot 4 Grafts (Prostheses). These prostheses were prepared as other Lot 4 grafts but using Prostheses Ivalon surgical sponge. This material exhibited the same excellent handling properties as the Clay Adams surgical sponge and sewed well. It was strong and pulsated slightly more than the aorta. It was considered to have the advantage of smaller and more uniform pore size. It molded well boiling in distilled water for 20 minutes.

Five dogs were implanted with tubes from this group. Four died after 2 to 7 days from bleeding and atelectasis. One graft had a small thrombus that originated at a defect in the distal portion of the graft. One dog lived for 2 months and died from unexplained causes. The graft was patent and well lined. External fixation was good.

#### HISTOPATHOLOGIC FINDINGS

**Wedges.** Three wedges prepared as described above and embedded for 6 weeks in subcutaneous tissue were examined. They were sectioned longitudinally and at three levels in the transverse plane. In all sections the interstices of the sponge were filled with connective tissue (fig. 2). There was no evidence of progression from the external surface toward the center. Slight differences among the three wedges were noted. In wedge A the fibrous tissue was more vascular with dilated capillaries and appeared to show younger granulation tissue than the other two. In wedge B the collagen fibers were larger and

less cellular, but there were a few more polymorphonuclear cells scattered about. In wedge C, the collagen was still more dense and mature. In all three, there were many foreign body giant cells. It is thought that perhaps wedge C, which was soaked in Zephiran Chloride solution and not washed, provoked the most violent inflammatory reaction, while wedge A, which was

Figure 1 Photographs of eight specimens all Lot 4. Although some resulted in very satisfactory vascular replacement (No 396 400 374) the disturbing finding of dilatation of the tube (No 336 376 337 and others) and the microscopic demonstration of disintegration of the plastic make this material unreliable. Some specimens show variable degrees of mural thrombosis even as long as one year after implantation.

not treated with Zephiran, provoked the least. This would explain the more rapid proliferation of granulation tissue. Continuing inflammation with the accumulation of neutrophils would hinder the formation of fibrous tissue, but the early stimulation of fibrin rich exudate would hasten the laying down of fibrous tissue.

Wedges that had been embedded for periods of 1 to 4 weeks also were examined. The 1 and 2 week specimens showed acute

Figure 2 At the top is shown early infiltration of the plast c by vascular connective tissue. The lower frame shows mature connective tissue filling the plast c interstices. Note the dark deposits of "mineral" material.

inflammatory reaction, while the 3 week specimens showed well developed vascular fibrous tissue in the plastic spaces. Trichrome stain showed collagen fibers and many foreign body giant cells. The 4 week specimens showed increased density of collagen and many giant cells. The change from inflammatory reaction to fibrosis apparently occurs between the second and third weeks (one second week specimen contained bacterial contamination which obliterated any early fibrous reaction that might have been occurring).

In many of the later specimens, there was a dark granular outline on the periphery of the sponge spicules. This dark material was at first thought to consist of cellular nuclei, but in later observations it was considered that it represented some type of mineral material lining the pores of the sponge. In the latest specimens, it resembled calcification.

**Aortic Grafts.** The various features observed in the aortic grafts can be grouped under seven headings:

1 *Evaluation of graft compactness.* An attempt was made to evaluate the ratio of Ivalon material to pore space, that is, the compactness of the graft. This proved to be extremely difficult and unreliable due to the inconstant shrinkage of the plastic.

2 *Inflammatory reaction.* The degree of inflammation in connective tissue immediately external to the Ivalon sponge varied considerably. In Lot 1, inflammation was marked even in the 120 day specimen. In Lot 3, there was considerable inflammatory reaction with active granulation tissue at 28 days, but there was no significant inflammation at 60 days and thereafter. In Lot 4, there was only slight reaction after 35 days and none in 42 days. Specimen No. 306 (fig. 1) showed red blood cells and polymorphonuclear leukocytes in the interstices, with no evidence of organization. This material had been implanted for 118 days. Absence of organization may be explained perhaps by the presence of infection. Similarly, specimen No. 100 at 9 months showed a layer of granulation tissue with heavy polymorphic infiltrate along the external surface. No. 337 at 12 months also showed polymorphonuclear cells in most of the plastic spaces within the graft as well as along the external surface. The other specimens showed no inflammatory reaction.

3 *Organization in interstices.* Specimens of Lot 1, even as long as 120 days after implantation, showed no organization. The spaces were filled with fibrin and blood cells. In Lot 3, there was slight organization in the outer spaces at 45 days. Complete organization in the outer one third of the Ivalon sponge was observed, however, at 60 to 75 days in both Lot 3 and Lot 4. It is interesting, however, that Lot 4 specimens showed good organization with mature connective tissue one half way through

1462 U. S. ARMED FORCES MEDICAL JOURNAL

4. Fixation to adjacent tissue None of the specimens of Lot 1 showed significant degrees of fixation. In Lot 2, one specimen showed some degree of fixation at 75 days and in Lot 3, a fair degree of fixation was evident at 60 days. Lot 4 showed much earlier fixation with evidence of good anchoring at 35 days and thereafter in the specimens from thoracic aorta, lung tissue was frequently seen on the external surface with good organization extending into the plastic.

5 *Lumina* The degree to which pseudo-intimal proliferation occurs (fig 3) varies considerably and does not show significant differences among the various lots. In general at 14 days the fibrin layer is covered by fusiform cells forming a rerebrined two to three cells thick. By 20 to 25 days this layer has thickened and extends approximately 1 mm from the end of the aorta. At 35 days it reached 2 mm at 45 days, 3 to 4 mm and at 60 days 5 mm. This layer at an early stage overlies fibrin and later bleeds into the fibrin that fills the length of the tube. It consists of both collagen and smooth muscle, with the former occurring in a higher proportion than in the corresponding layer of the neighboring aorta. Although fine elastic fibers were seen in the thickened intima of the adjacent aorta, none were seen in the intima like tissue within the graft. The major elastic layer of the media stopped abruptly at the cut end of the aorta. At 4 foci of inorganic phosphorus deposits appeared in the pseudo-intima and the graft at 35 to 40 days. At 5 to 12 months the luminal surface of the thickened

Lot 4 foci of inorganic and the frequently

beyond the cut end of the aorta

6 to 10 changes. The changes noted in the aorta although quite variable seemed to have no relation to the lot number but appeared to depend upon the degree of trauma inflicted on the vessel ends. In many specimens hyaline necrosis appeared at the cut ends in from 4 to 6 days. Most of the specimens showed some degree of intimal thickening one as early as 6 days. In another however there was no thickening at 27 days. In general thickening was present at 20 to 25 days and

Figure 3 Sections across the junction of plastic to vessel show formation of the pseudointimal layer. The upper photograph shows early ingrowth of fibroblasts into the fibrin layer. Note the abrupt termination of the elastica (upper left corner). The lower illustration shows a pseudointima of mature connective tissue. Note the state of the plastic material at bottom of both frames. The upper specimen is 27 days and the lower 42 days after implantation.

Figure 4 The calcific deposit beneath the luminal layer at 35 days is shown in the left upper illustration. On the right a well developed fibrous external layer is seen and there is calcific material at the edge of the plastic (8 months). The lower illustration shows extensive disintegration of plastic and replacement with calcific material (11 months).

was marked in the 10- to 45 day specimens. In one specimen, at 120 days, there was extreme thickening, together with calcific deposits in the media near the cut ends. In several specimens, there were focal areas of thickening away from the cut ends, and in one 35 day specimen from Lot 1 there also was some calcium in the media of the aorta. Elastic tissue stains showed that in earlier examples there were no elastic fibers, or at most very fine fibrils running in all directions and possibly representing reticular fibers. In the later specimens, however, there were well defined elastic fibers oriented longitudinally but not as heavy as the normal elastic tissue of the media. There were two specimens in which a very few fine fibrils appeared to extend from the junction of the aorta and graft for a short distance into the pseudointima. These may represent regenerated elastic fibers.

*7 Changes in the plastic.* The most significant and undesirable changes noted (fig. 1) were as follows. Dark deposits suggestive of calcification first appeared on the edges of the plastic spicules at 6 to 8 weeks. Several specimens showed layers of finely divided calcific material between the plastic and luminal layer at 5 and 6 weeks. Variable amounts of this material were seen in all specimens, until at 8 to 9 months the plastic seemed to be coated by frankly mineral material, in the sense that the investing material had a refractile appearance. At 10 and 11 months, the plastic was undergoing obvious disintegration. This seemed unrelated to inflammatory change, because one specimen at 12 months showed considerable inflammatory reaction but no plastic degeneration. These changes were also unrelated to the lot number of the grafts.

### SUMMARY AND CONCLUSIONS

The physical properties of Ivalon (polyvinyl formal sponge) appeared to offer certain advantages not available with other materials for use in replacing vascular segments. To test this, four types of Ivalon sponge were obtained from three different manufacturers and prostheses were prepared by boiling or dry heat, using various techniques. These were implanted in mongrel dogs as abdominal or thoracic aortic grafts.

The Rubatex product proved to be unsatisfactory for vascular replacement, not only on the basis of difficulty in fabrication of the tubes but also because it appeared to be less well tolerated by tissue and less satisfactorily infiltrated by collagen material. It was associated with inflammatory reactions more frequently than were the other two types of Ivalon. The Clay Adams and Prosthesex materials were good from the standpoint of fabrication of the prostheses as well as in regard to tissue tolerance. The most serious limitation to the use of these materials is indicated by late changes seen at 10 months and consisting of extensive disintegration or fragmentation of the graft material. It appears

## U. S. ARMED FORCES MEDICAL JOURNAL

that such a process can only lead to eventual disruption of the grafted segment, because fibrous scar tissue alone and unsupported eventually undergoes aneurysmal dilatation.

Technically, tubes of Lots 3 and 4 were satisfactory. Suture qualities, initial pliability, elasticity, and porosity were excellent. However, gross examination of these implants at a very few weeks showed loss of elasticity, reduction of wall thickness, brittleness and discoloration of the plastic, and sometimes slight reductions of caliber of the tube. In a few late specimens, there was evidence of plastic disintegration described microscopically. The finding of early clotting or thrombosis was very high in the first lots used in the abdominal aorta. Occlusion by thrombosis in the thoracic implants did not occur, except in the case of one animal that died with empyema a few days after the operation. There were, however, several specimens which showed varying degrees of mural thrombosis.

In one of the pilot experiments, disruption of the spirally wound prosthetic occurred, resulting in fatal hemorrhage. In none of the other animals was there rupture or separation of the plastic material.

The use of the pump shunt during occlusion of the thoracic aorta has many advantages over the use of hypothermia, but the need for using heparin makes hemostasis very difficult particularly with regard to blood oozing through the pores of the graft. Immersion of the sponge in nonheparinized blood before implantation might be a means of minimizing this disadvantage. This technic should be further evaluated.

# REDUCTION OF IONIZING RADIATION IN DIAGNOSTIC ROENTGENOLOGY

ARCHIBALD G. M. MARTIN III *Lieutenant Colonel USAF (MC)*

THE UNITED Nations Scientific Committee on Effects of Atomic Radiation<sup>1</sup> recently expressed its desire to receive information as to the methods and extent by which economy in the medical use of radiation could be achieved, both by avoiding examinations that were not clearly indicated and by decreasing the exposure to radiation during examinations, particularly if the gonads or the fetus during pregnancy lie in the direct beam of radiation. The Committee concluded rather logically "It appears most important, therefore, that medical irradiations of any form should be restricted to those which are of value and importance, either in investigation or in treatment, so that the irradiation of the population may be minimized without any impairment of the efficient medical use of radiation."

The use of irradiation in industry, engineering, and allied professions has greatly enhanced the possibility for individual exposure, both known and unknown. Young people, particularly, should attempt to learn the type and quantity of the exposure to which they have been subjected, and this should be evaluated before extensive, diagnostic, medical irradiation is contemplated. Each patient requiring therapeutic treatment should be studied minutely. Quimby and Lawrence<sup>2</sup> in 1940 and Henschaw<sup>3</sup> in 1946 have set down rather specific definitions for exposure or dose.

Probably the most publicized and misinterpreted report on the biological effects of atomic radiation is that of the National Academy of Sciences. The section by the Committee on Genetic Effects of Atomic Radiation stated "First, although the science of genetics is as precise and as advanced as any part of biology, it has in general, and particularly in human genetics, not yet advanced far enough so that it is possible to give at this time precise and definite answers to the questions just how undesirable, how dangerous are the various levels of radiation, just what unfortunate results would occur?" The scientists cannot say with exact precision just what biological risks are involved in

---

From U. S. Air Force Hospital, Harlingen Air Force Base, Harlingen, Tex.

various levels and sorts of radiation exposure. When a gene becomes permanently altered we say it mutates. The gene in its altered form is then duplicated in each subsequent cell division. If the mutant gene is in an ordinary body cell then it is rarely passed along to other body cells but the mutant gene, under these circumstances is not passed on to progeny and the effect of the mutant gene is limited to the person in whom the mutation occurred.

It cannot safely be assured however that the effect is a negligible one on the person in whom the mutation occurred nor can it be said that this effect is non-genetic even though passage to offspring is not involved. Various kinds of cellular abnormalities are known to be perpetuated within an individual through body cell divisions so these effects are genetic in the broad sense.

Individuals bearing harmful mutations are handicapped relative to the rest of the population in that they tend to have fewer children or to die earlier. Hence such genes are eventually eliminated—soon if they do great harm more slowly if only slightly harmful. A mildly deleterious gene eventually may do just as much total damage as a grossly or abruptly harmful one because the milder mutant gene persists longer and has a chance to harm more people.

Although many mutations do disturb normal embryonic growth it is not correct that all or even that most mutations com only result in monstrosities or freaks. In fact the commonest mutation is those with the smallest direct effect on any one generation—the slightest detrimental. The last remark deals with all types of radiation induced mutations however there are others such as mutations that arise from natural causes. These naturally occurring and hence unavoidable mutations are called spontaneous mutations. As with radiation induced mutations nearly all of the effects of spontaneous mutations are usually thought to be harmful. It has been stated that about 2 per cent of tangible genetic defects—which include certain mental defects—epilepsy malfunctions neurovascular defects and many others—are present at birth or appear before sexual maturity. If man made radiation increases the mutations by a "doubling dose" with an increase from two million defects to four million defects approximately 200 000 new tangible defects should occur in the first generation.

The total dose of radiation is what counts. This statement is based on the fact that genetic damage done by radiation is cumulative. The geneticists also conclude that mildly larger doses of radiation would produce more but not worse mutants.

The genetic importance to a child is the total radiation dose that the child's parents have received from their conception to the conception of the child. It seems sensible to use a round figure of 30 years in this connection, especially since this figure is the one usually chosen to measure a generation.<sup>4</sup>

Most studies on mutation from exposure to radiation has been done on the genes of the mouse and the fruit fly. Unfortunately, geneticists have assumed that mouse and fruit fly statistics apply reasonably well to man. It seems necessary to emphasize this matter of approximate estimation, so that no one will conclude improperly that a statement is unreliable because it involves a range of values. On the contrary, such a statement, when made in a situation like the present one, should be viewed as all the more dependable precisely because it does not pretend to an unwarranted accuracy. Henshaw, in discussing the radiation induced mutants in human beings, stated "With the possibility of irradiation induced mutations appearing so likely, why are abnormalities not seen more often in the offspring of individuals exposed to radiation? Two possible explanations will be offered here and others will become apparent later. First, irradiation induced mutations result in changes which are often identical with changes which arise spontaneously making the detection of abnormalities resulting from exposure to radiation dependent upon statistical evaluations. Some statistical studies have been made but, although a small amount of positive evidence has been obtained, the data are so limited they have little meaning. Second, many mutations are recessive in character and, since the possibility of two similar mutant genes coming together in the same individual is very remote at first, the process of production of such genes must be in operation a long time before recessive characters can be manifested in appreciable numbers."

Many scientists have tried to develop the lowest figure that could be responsibly considered an acceptable dose rate. Various arguments reduced the 5 r to 150 r range and several experienced geneticists have recently made estimates in the narrower range of 30 r to 80 r. The National Academy of Science recommended "that the general public of the United States be protected, by whatever controls may prove necessary, from receiving a total reproductive lifetime dose (conception to age 30) of more than 10 roentgens of man made radiation to the reproductive cells. Of this reasonable (not harmless, mind you, but reasonable) quota of 10 roentgens over and beyond the inevitable background of radiation from natural causes, we are now using on the average some 3 or 4 roentgens for medical X rays. This is roughly the same as the unavoidable dose received from background radia

various levels and sorts of radiation exposure become permanently altered we say it mutates. The gene in its altered form is then duplicated in every subsequent cell division. If the mutant gene is in an ordinary body cell then it is merely passed along to other body cells, but the mutant gene under these circumstances is not passed on to progeny and the effect of the mutant gene is limited to the person in whom the mutation occurred."

It cannot safely be assumed however that the effect is a negligible one on the person in whom the mutation occurred nor can it be said that this effect is nongenetic even though passage to offspring is not involved. Various kinds of cellular abnormalities are known to be perpetuated within an individual through body cell divisions so these effects are genetic in the broad sense.

Individuals bearing harmful mutations are handicapped relative to the rest of the population in that they tend to have fewer children or to die earlier. Hence such genes are eventually eliminated—soon if they do great harm more slowly if only slightly harmful. A mildly deleterious gene eventually may do just as much total damage as a grossly or abruptly harmful one because the milder mutant gene persists longer and has a chance to harm more people.

Although many mutations do disturb normal embryonic growth it is not correct that all or even that most mutations commonly result in monstrosities or frenzies. In fact the commonest mutations are those with the smallest direct effect on any one generation—the slightest detrimental. The last remark deals with all types of radiation induced mutations however there are others such as mutations that arise from natural causes. These naturally occurring mutations are usually called spontaneous mutations. As with radiation induced mutations nearly all of the effects of spontaneous mutations are thought to be harmful. It has been stated that about 2 per cent of tangible genetic defects—which include certain mental defects, epilepsy, malfunctions neuromuscular defects and many others—are present at birth or appear before sexual maturity. If man made radiation increases the mutations by a "doubling dose" with an increase from two million defects to four million defects approximately 200 000 new tangible defects should occur in the first generation.

The total dose of radiation is what counts. This statement is based on the fact that genetic damage done by radiation is cumulative. The geneticists also conclude that mildly larger doses of radiation would produce more but not worse mutants.

The genetic importance to a child is the total radiation dose that the child's parents have received from their conception to the conception of the child. It seems sensible to use a round figure of 30 years in this connection, especially since this figure is the one usually chosen to measure a generation.<sup>4</sup>

Most studies on mutation from exposure to radiation has been done on the genes of the mouse and the fruit fly. Unfortunately, geneticists have assumed that mouse and fruit fly statistics apply reasonably well to man. It seems necessary to emphasize this matter of approximate estimation, so that no one will conclude improperly that a statement is unreliable because it involves a range of values. On the contrary, such a statement, when made in a situation like the present one, should be viewed as all the more dependable precisely because it does not pretend to an unwarranted accuracy. Henshaw, in discussing the radiation induced mutants in human beings, stated "With the possibility of irradiation induced mutations appearing so likely, why are abnormalities not seen more often in the offspring of individuals exposed to radiation? Two possible explanations will be offered here and others will become apparent later. First irradiation induced mutations result in changes which are often identical with changes which arise spontaneously, making the detection of abnormalities resulting from exposure to radiation dependent upon statistical evaluations. Some statistical studies have been made but, although a small amount of positive evidence has been obtained the data are so limited they have little meaning. Second, many mutations are recessive in character and, since the possibility of two similar mutant genes coming together in the same individual is very remote at first, the process of production of such genes must be in operation a long time before recessive characters can be manifested in appreciable numbers."<sup>5</sup>

Many scientists have tried to develop the lowest figure that could be responsibly considered an acceptable dose rate. Various arguments reduced the 5 r to 150 r range and several experienced geneticists have recently made estimates in the narrower range of 30 r to 80 r. The National Academy of Sciences recommended "that the general public of the United States be protected, by whatever controls may prove necessary, from receiving a total reproductive lifetime dose (conception to age 30) of more than 10 roentgens of man made radiation to the reproductive cells. Of this reasonable (not harmless, mind you, but reasonable) quota of 10 roentgens over and beyond the inevitable background of radiation from natural causes, we are now using on the average some 3 or 4 roentgens for medical X rays. This is roughly the same as the unavoidable dose received from background radia-

tion." The 10 roentgen recommendation applies in an average sense to the population as a whole.

One should consider the findings of Macht and Lawrence<sup>1</sup> in 5,461 offspring of radiologists and exposed controls, there were 2.56 per cent twins, 14.03 per cent fetal deaths and 6.01 per cent congenital defects. In 4,484 offspring of unexposed controls, there were 2.1 per cent twins, 12.22 per cent fetal deaths and 4.02 per cent congenital defects. Normal offspring constituted 83.23 per cent of the unexposed group, as compared to 80.42 per cent normal offspring of the exposed group. In 328 offspring of radiation exposed fathers, 348 congenital defects were reported, while 229 congenital defects were reported in 216 offspring who were born of fathers unexposed to radiation. All types of defects were reported. Anomalies of the sense organs occurred with greatest frequency among both the exposed and the unexposed groups, and represented 17.53 per cent and 18.34 per cent, respectively of all anomalies reported. The offspring of exposed persons showed a significantly higher proportion of heart blood vessel and blood anomalies than the offspring of unexposed persons. The data given in the Macht and Lawrence report present a picture of first generation effects only. They concluded that the results indicate that small prolonged doses of radiation produce abnormalities in humans.

The problems of radiation protection in diagnostic roentgenology have been discussed carefully by Miller,<sup>2</sup> Henny,<sup>3</sup> and Ritter, Warren and Pendergrass.<sup>4</sup> Only by studying the relatively specific dosages due to diagnostic procedures can we develop a program of reduction of total radiation exposure. (We consider roentgen therapy as being a specific mode of therapy, and its additive ionization a medical necessity.) Fluoroscopic dosages usually amount to 10 to 20 r per minute in air, at the point of entry into the patient's body. It is important to note that most of the dosages given are at the skin in air and do not represent the final dose on the reproductive organs or hematopoietic tissue. For example, in taking an anteroposterior film of the pelvis, 5.3 r at the skin measure only 0.6 r at the ovary exposure. At the other end of the diagnostic range is the usual chest film with only 0.05 r dosage. In securing a gastrointestinal series, the total exposure includes both the fluoroscopy and the film studies. Dental films average about 5 r each. This latter exposure probably means very little genetically as only 0.005 r reaches the gonads.

Changes in instrument design cannot be controlled at this stage by the average practicing radiologist and although the

prospect of new developments in roentgenoscopic image amplification should be mentioned, the primary purpose of this report is to discuss specific methods for avoiding exposure to radiation during the usual radiologic examination.

No data covering large numbers of technicians working in radiologic facilities are available, however, the report of Mecht and Lawrence<sup>2</sup> points up the fact that the training of radiologic personnel is a cardinal requisite in the reduction of exposure to ionizing radiation. Besides the dogmatic teaching of the principles of radiation, instruction in the use of shielding, coning, positioning, and filters, and in the selection of techniques is of great importance. During an exposure, technicians must always move behind a shield. Although distance is a great shielding factor, the habit of specific shielding should not be compromised. Shielding of operating personnel in such procedures as angiocardiography, encephalography, and cardiac catheterization must be adhered to. Good lead aprons will suffice. The use of cones to reduce irradiation other than that essential for the making of roentgenograms is well known. Technicians must be taught to position patients and to utilize correct techniques in order to obtain the best possible film at the first exposure. Repetition of exposures cannot be tolerated with our present apparatus, techniques, and mechanical aids. Close liaison between the radiologist and his technicians in selection of the correct techniques and positions will eliminate multiple exposures. The use of additional filtration such as 1 to 2 mm of aluminum has been well established. Filters should be used in both fluoroscopic and diagnostic machines.

Local shielding of the gonads has been employed in our department with good success. It is well accepted by personnel, readily available, easily accomplished, and detracts only moderately from the diagnostic value of the finished film. It cannot be denied that the male military population can be much more simply protected than can the patients of large city hospitals, in which the sexes examined are more equal in number. Although exposure during an upright anteroposterior examination of the chest is only approximately 0.05 r because of the 72 inch distance, minute amounts of radiation could conceivably affect the gonads. At the present time, a small lead apron made from the usual radiologist's apron is attached at the belt line. This may be of more value in teaching personnel the facts concerning radiation than in actual measurable protection from radiation which according to Chamberlain<sup>3</sup> as reported by Perkins<sup>4</sup> is 0.00025 r to the gonad.

During intravenous pyelographic examination, the testes are shielded quite simply, and this does not detract from the diag-

notic value of the film. We have been unable to devise adequate protection of the ovaries. Use of the shield as in a roentgenographic study is being tried in the low back study which consists of anteroposterior films, oblique films, and spot films of the lumbosacral space in the lateral view. The rule is more readily susceptible to protection in this examination. The number of exposures in the follow up examination of the small bowel study in children have been decreased. Shielding has not retarded the careful perusal of film made periodically during this examination.

The story of the excited grandmother who phoned the radiologist refusing to submit to roentgen ray examination because it might affect her grandchildren through her genes is ludicrous but might serve to highlight several points. One in patients beyond childbearing age the problem of gonadal exposure is actually no real problem and two it should be borne in mind that frequently older patients are those who require the most extensive or prolonged studies. We feel that the older patients in the "cancer state" deserve special diagnostic studies. In a way, the radiation to which this group is exposed falls into the same category as radiotracer "must have" type of medical procedure.

Attention to the physical factors of technique by the roentgen ray technician under the guidance of the radiologist, is another way in which total exposure may be reduced. The changing of high milliamperage to high kilovoltage and low milliamperage techniques substantially reduces total irradiation without loss of diagnostic value of the films. This is of particular value in children in whom because of their small size and the desire to see more on one film large areas are frequently radiated. The use of small fields even in the small child is to be preferred. As mentioned by Henry, the integral dose at 60 kv is 1.1 times as great, and at 50 kv is 5.1 times as great as at 100 kv for the same film density.

Avoidance of any radiographic procedures that might expose the abdomen in early pregnancy should be especially seriously considered. Not only the maternal ovaries but the fetal gonads receive a moderate dose. For example Sowby<sup>11</sup> found that in pelvimetry the fetus received 26.65 r and the maternal ovary 1.25 r while in a pyelogram as much as 3.21 r reached the ovary. Actually so little can be learned by doing pelvic measurements early that this procedure should be reserved until the last trimester when more information may be gained concerning not only the maternal pelvis but also the fetus and placenta.

Production of roentgenograms with reduced exposure by the method of intensification by toning is relatively simple and inex-

pensive, but has not been used advantageously. Intensification may be used when it is necessary to reduce the quantity of the radiation or to use shorter exposure time, or when it is impracticable to use heavy, high powered apparatus. We are also using this method to render interpretable those films that were technically impossible to study.

The advantageous use of fluoroscopy and the selection of films to be made must be reviewed. In the past, multiple films and spot films "for the record" were made as a backup procedure in many clinics. It is much more important that careful selection of positive as well as negative findings be made and that the number of exposures be reduced. In our present state of enlightenment, the old procedure of taking many films in the hope of finding a diagnosis must be abandoned. Equally as important as selection of technique and reduction in number of films is avoidance of repeating examinations. Technicians particularly, and radiologists also, must avoid the pitfall of having "another look" if the diagnosis is not altogether clear, or of satisfying the human whim of getting perfect pictures on the celluloid. Excellence in technique, not repetition is the answer to this problem.

Lastly, a few words on education with respect to irradiation. A scare program can be very detrimental to good diagnostic roentgenology. Data from those qualified to speak should be made available and publicized. Early education of technicians and patients is mandatory and acceptable in this atomic era.

Most of the procedures outlined above are practiced daily by competent radiologists and their technicians. Awareness and continuation of good, sound practices that have been used for years by radiologists are probably the only methods for reducing diagnostic irradiation at the present time. A survey of each diagnostic, radiologic department is indicated. Based on the number of exposures of various types, reduction can be concentrated in specific directions. Special effort must be expended toward reducing irradiation in examinations involving exposure of the gonads primarily; studies of the lumbar spine, pelvis, coccyx, hips and upper femur; and fluoroscopic examinations of the gastrointestinal tract, urinary tract, and reproductive tracts, as well as visualization of the gallbladder, spleen, and liver.

In this small Air Force hospital, roentgen exposure and sites by frequency of occurrence include chest, hands, feet, ankles, knees, and wrists, in the order listed. The experience in each department may indicate that the problem of reduction of irradiation is not as urgent as previously considered. Exposure to the gonads is considered inherent in the examination of the lumbar spine, pelvis, coccyx, hips, and femur, in pelvimetry, gastro

intestinal examination and examinations of the urinary tract. Actual measurements in our laboratory are not inconsistent with findings at larger teaching institutions, and show that changes in technique to include high kilovoltage and low milliamperage, as well as diminution in the number of films will reduce the total amount of ionizing irradiations to the gonads.

This subject has been of such general interest to the public and the medical profession that, writing in the lay press, Dr Dwight H. Murray, then President of the American Medical Association, stated "Control and standardization of the way X rays are being used in medicine today are in the hands of highly skilled specialists known as radiologists. When X rays, radium and the radioactive substances, such as isotopes are used by specially trained doctors of medicine they can be termed safe although there is some risk in every form of medical or surgical treatment. The hazards of radiation therapy are extremely small however, in the less serious diseases. They are one of medicine's great gifts both in treatment and cure. In the hands of skilled radiologists they promise to give you added years of comfort and life."

### SUMMARY AND CONCLUSIONS

A review of current scientific and medical pronouncements on the effects of ionizing radiation has been made and modern radiologic practices have been examined. The following conclusions have been reached: (1) With the knowledge that we already have we can adequately protect both patients and personnel by the proper use of cones, diaphragms, filters, accurate technique, short exposure time and the proper use of shielding. (2) Medical use of ionizing irradiations for diagnosis and therapy has been well established. (3) Alteration of the genes in the gonads by mutation is known to occur and by approximate estimates can be referred to man. (4) Total irradiation of patients is cumulative and must be reduced. (5) From the diagnostic radiologic standpoint total irradiation may be reduced by a renewed awareness of the best radiologic technique and practices used at the present time.

### SARCOIDOSIS AND PREGNANCY

"In following the course of 10 patients with sarcoidosis through 16 pregnancies, it was observed that pregnancy appears to have an ameliorating effect on sarcoidosis during the prenatal period but that this benefit is frequently lost after delivery. All the patients tolerated pregnancy well, however, there were two abnormalities of pregnancy and three fetal abnormalities noted in the 16 pregnancies. The observed improvement of the sarcoidosis during pregnancy might constitute evidence against tuberculosis being the etiology of sarcoidosis since pregnancy does not improve, and may even aggravate tuberculosis. It is possible that improvement of sarcoidosis during pregnancy is due to the increase in production of corticoids by the adrenal glands during gestation."

## Clinicopathologic Conference

William Beaumont Army Hospital Fort Bliss Tex \*

### HEADACHE AND INTERMITTENT PARESIS

**Summary of Clinical History** A 45 year old white woman had a sudden onset of sharp severe, throbbing right temporal head ache on the morning of admission to this hospital. The headache remained severe was made worse by any movement and was not particularly relieved by anything including aspirin. Shortly before admission she began noting slurring of speech and equal weakness of the left arm and left leg causing unsteadiness of gait. She did not lose consciousness. There had been no previous paresis syncope anesthesia or memory loss.

The patient had pneumonia in 1950, possibly associated with pleural fluid, and followed by a chronic cough productive of dark thick material but without hemoptysis. The patient was known to have hypertension since 1949. She also had had exertional dyspnea and ankle edema for the past year and a half. The patient had been unconscious for a very brief interval following an automobile accident in 1948. She was released from a hospital in a few days.

**Physical Examination** The patient was a well developed, fairly well nourished white woman who was somewhat lethargic had slight dysarthria and complained of severe right temporal head

At the time of the conference Col Ab Zehm MC USA was Commanding Officer  
From the Laboratory Service Maj Joh A Furst MC USA Chief of the Laboratory Service  
Honor Hospital Erie Pa

her pulse rate was 81 per minute and her blood pressure 184/110 mm Hg. The optic disks were normal. The fundic arterioles were spastic with a 1:1 venous arteriole ratio. No hemorrhages or exudates were noted. The teeth were partially absent and the gums appeared unhealthy. The tongue deviated to the left and a gag reflex was present. The breasts were normal. The lungs were slightly hyperresonant to percussion and had coarse rales throughout. Examination of the posterior chest was unsatisfactory because the patient was in decubitus position. The point of maximal cardiac impact was palpable and visible 10 cm from the midsternal line in the sixth intercostal space. The mitral first sound was widely split. The liver was palpable two to three fingersbreadth below the right costal margin. There were no abdominal masses or tenderness. A lower abdominal scar was well healed. Neuromuscular reflex reactions were right biceps 2 plus, left 3 plus, right triceps 2 plus, left 3 plus, right knee jerk 2 plus, left 3 plus, right and left ankle jerk, 0, absent Babinski bilaterally, and Gordon and Oppenheim both 1 plus bilaterally. There was left facial paralysis, and weakness and flaccidity of the left arm and leg.

**Laboratory Studies** The urine had a neutral reaction and normal albumin and sugar. Microscopic examination of the urine disclosed many epithelial cells, 3 to 5 white blood cells, and an occasional red blood cell per high power field. White blood cell count was 10,200/ $\mu$ l, with 71 per cent neutrophils (6 per cent band forms), 22 per cent lymphocytes, and 7 per cent monocytes. The red blood cells numbered 4,680,000/ $\mu$ l and the hemoglobin was 13.2 grams/100 ml. The spinal fluid three days after admission was clear with a cell count of 237 white blood cells/ $\mu$ l (10 per cent neutrophils and 90 per cent lymphocytes), total protein of 100 mg/100 ml, colloidal gold 1:12333110, and the serologic test for syphilis was negative. A blood cardiolipin test was negative. Six days after admission the spinal fluid was clear with a white blood cell count of 45/ $\mu$ l, sugar, 55 mg/100 ml, total protein, 72 mg/100 ml, colloidal gold, 0001220000, and chlorides, 729 mg/100 ml.

A roentgenogram of the chest disclosed normal lung fields. The bones of the skull were normal on a roentgenogram. A calcified pineal was in normal position. A deep Q wave in lead III on an electrocardiogram was probably positional, in absence of significant Q wave in lead aVF. A slightly prolonged Q-T interval suggested myocardial disease or uremia.

**Course in Hospital** The morning after admission the patient had involuntary urination and defecation, but had called for a bathroom. Her left arm and left leg gradually increased in strength.

The headaches gradually decreased in severity and she became more alert so that upon discharge she was able to walk and could talk intelligently. There was however a residual headache. She was given a rice diet and the blood pressure dropped, at the time of discharge it was 110/70 mm Hg. The trend of the findings on spinal fluid examination indicated a vascular disorder. She was instructed to remain on the rice diet and take 30 mg of phenobarbital four times daily, 90 mg of papaverine three times daily, and a multivitamin preparation once daily.

Fifteen days after this first admission the patient was seen in the receiving office. It was obvious that she was no better than she had been previously. Neurologic examination failed to reveal any progression of signs. The pupils were extremely small and it was believed that the patient might have been taking heavy medication for her severe headache. She was admitted for a detailed neurologic study. On this admission, the patient stated that her mother had died with a similar paralysis. That evening the patient was able to walk with support. The next morning she was very lethargic and unable to converse intelligently. Her blood pressure was 210/100 mm Hg and her pulse 72 per minute. There was Cheyne Stokes respiration and she was incontinent. The neurologic examination had changed in that the right pupil was widely dilated and the patient had vomited. A blood bromide level on this second day was 15 mg/100 ml. The patient died quietly the day after admission.

### DISCUSSION

**Doctor Schoerer:** This 45 year old white female patient was admitted with a history and a clinical picture that would immediately suggest a diagnosis of a stroke. Her past history shows that she had pneumonia in June 1950 from which she recovered. Furthermore the patient had been a known hypertensive since 1949. During the past year and a half she had exertional dyspnea and ankle edema which together with the fact that her liver and heart were moderately enlarged would seem to suggest early congestive heart failure. The terms *apoplexy*, *CVA* and *stroke* are used interchangeably in describing a picture such as the one presented by this patient. These terms merely imply that something of sudden nature has happened in the patient's central nervous system causing him or her to be paralyzed. The term *CVA* indicates that this "something" was accidental in nature which in most cases is incorrect. *CVA* is an ugly abbreviation which should be dropped from our vocabulary. All of these terms tend to lull the physician into a state of mind where he assumes to have established a satisfactory diagnosis usually resulting in therapeutic nihilism of prescribing vitamins and some

vasodilating drugs of questionable value. One should keep in mind that many conditions may give rise to similar neurologic syndromes and that the neurologic signs and symptoms merely tell where the lesion is but not what the lesion is due to.

The differentiation of the cause of the clinical picture has become more important in recent years since depending on the exact underlying process different measures will have to be instituted. Sudden onset of severe throbbing headache followed within a matter of hours by symptoms of paralysis almost certainly indicates vascular disease. We now shall consider the differential diagnosis of cerebral vascular disease with major neurologic symptoms. Differential diagnosis as to pathogenesis is fairly simple, but the etiologic possibilities are myriad. Disturbances in circulation are by far the most common of all the organic cerebral diseases. Spontaneous cerebral vascular lesions rank third or fourth among the causes of death in the United States. The pathogenic mechanisms involved can be reduced to four main ones: first, thrombosis, second hemorrhage, third embolism and fourth, so called vasogenic encephalopathy characterized by histologic findings of ischemic damage to the brain tissue without obvious occlusion of any large blood vessels.

The clinical pictures presented by these mechanisms are very similar. The difference is more a quantitative than a qualitative one. The most common of the four mechanisms is thrombosis followed by hemorrhage, and embolism the least frequent. Vasogenic encephalopathy is probably more common than usually realized and may be even more common than thrombosis. Most valuable information as to type of lesion is to be obtained from an accurate history. Prodromal symptoms, for instance, may be absent in embolism. In thrombosis and hemorrhage they are very similar. Both categories may produce headache, dizziness, and paresthesias.

In thrombosis chronic personality changes may be more common than in hemorrhage whereas in the latter, vomiting, convulsions, loss of sphincter tone and loss of consciousness are frequently encountered at the time of actual hemorrhage. Thrombosis in the absence of prodromal symptoms with a sudden dramatic onset may simulate hemorrhage. One would expect vasogenic encephalopathy to produce the mildest picture of the three but again cases have gone on to actual death without any histologic evidence of thrombosis but with the picture of diffuse ischemia of the brain. The most common causes of thrombosis are arteriosclerosis, syphilis, arteritis obliterans, periarthritis nodosa, polycythemia, sickle cell anemia, leukemia, and shock. The resulting tissue damage is characterized by softening and edema of the brain tissue at times simulating the picture of a tumor. Thrombosis is seen somewhat more frequently in males than in females and occurs most commonly during the fifth and sixth decades. Hemorrhage and hypertension with or without arteriosclerosis is often seen.

Vascular disease without hypertension and trauma aneurysm vascular tumors and blood dyscrasias must be considered particularly if faced with a young individual aneurysm is a serious consideration. At times it may be almost impossible to decide whether one is dealing with a hemorrhage into an infarcted area or with a primary hemorrhage. In hemorrhage the initial lesion may be intimal hemorrhage into the cerebral vessel wall similar to those seen in coronary vessels. A distant perivascular extravasation in the pons and medulla probably is merely a reflection of the suddenness and violence with which the pathologic event causes a sudden increase in intracranial pressure followed by temporal lobe herniation and possibly a cerebellar herniation.

Vasogenic encephalopathy is commonly seen in patients with either hypertensive arteriosclerosis or renal disease. It is thought that the ischemic changes found are the result of vascular spasms or the result of sudden drops in blood pressure as for instance in patients with myocardial infarction or patients in severe shock. Angiographic studies in patients with aneurysms have demonstrated vascular spasm to occur commonly in blood vessel receiving the aneurysm. Focal signs in patients with subarachnoid hemorrhage due to ruptured aneurysm may be due to hemorrhage into cerebral tissue or and probably more common due to spasm in the neighboring arteries. In cases where such vaso spasm leads to permanent functional loss one would have to assume that a protective mechanism has overshot its goal.

Sudden cerebral symptoms which tend to improve also occur in the following conditions which have to be considered in the differential diagnosis. (1) Subdural and extradural hematomas in the absence of a traumatic history would not be very high on the list although chronic subdural hematoma may occur without history of trauma. These patients usually present histories of chronic headache. Their condition shows fluctuation and actual neurologic changes occur more or less gradually. (2) A malignant infiltratively growing brain tumor may exist for considerable time without causing any symptoms. Sudden hemorrhage into the tumor tissue may simulate a mere brain hemorrhage. Some of these tumors are also known to have a tendency to cause thrombosis. The main feature of thrombosis or hemorrhage with brain tumor would be progression of disease rather than a tendency to improve following the initial attack. The possibility of brain tumor would have to be seriously considered in our case. (3) Brain abscess has a tendency to simulate brain tumor. Not infrequently the patient shows evidence of a focus of infection such as bronchiectasis however brain abscess if well encapsulated may not cause a febrile picture. Changes in the spinal fluid such as marked pleocytosis are commonly seen the blood picture most commonly shows a definite increase of the white cell count as seen with abscesses elsewhere in the body. (4) Postconvulsive paralysis usually does not present any diagnostic difficulties in

the face of an epileptic history (5) Multiple sclerosis rarely may simulate an apoplectic attack (6) Adams Stokes syndrome (7) Carotid sinus syncope (8) Extracranial carotid thrombosis This last condition definitely enters into differential diagnoses The symptoms produced by it are very protean and range from almost nothing to severe mental deterioration the typical picture being a hemiparesis with unilateral blindness the clinical picture depending entirely on the possibilities of collateral circulation in a given case (9) In a comatose patient diabetic uremic and hypoglycemic coma must be considered (10) Poisonings particularly lead poisoning may lead to vascular disease and hypertension which in turn may cause one of the mechanisms previously discussed

In addition to the history and physical and neurologic examinations it may become necessary to have blood and urine, blood chemistry, cerebrospinal fluid, electroencephalographic angiographic and air studies in order to pin a certain cause to any given clinical picture We may now examine our protocol as to possible clues to the cause, but we are not very richly rewarded There is hardly any doubt that the underlying mechanism is a vascular one and as far as mechanism is concerned we will have to consider thrombosis, hemorrhage, and vasogenic encephalopathy Since there is no obvious source of embolism I think we can rule this out Thrombosis, hemorrhage, and hemorrhage in to a brain tumor are all good possibilities The absence of a bloody spinal fluid is more in favor of thrombosis The fact that the calcified pineal is in a normal position makes the presence of a brain tumor rather unlikely although a brain tumor of infiltrative type may not cause a shift of the pineal

The laboratory data show some spinal fluid abnormalities which demonstrate a tendency to clear up between the third and sixth day of the first hospitalization and are such as very well may be seen with ischemia to brain tissue They do not seem to be diagnostic The neurologic examination merely indicates that the right hemisphere is involved The neurologic picture presented is not characteristic of occlusion of any particular intracerebral artery The patient was a known hypertensive and as such was predisposed to either thrombosis or hemorrhage The possibility that this patient may have had an aneurysm that at first merely caused vascular spasm and finally ruptured also has to be considered Syphilis as a possible cause of thrombosis may be ruled out in the absence of positive serologic reaction and a colloidal gold curve which in the spinal fluid obtained on the third day of hospitalization showed a mildly parenchymatous type of curve and within three days went back to normal without any specific therapy The patient died in a manner indicating sudden increase of intracranial pressure in the right hemisphere, respiratory failure, temporal lobe herniation and possible cerebellar herniation Again this could be the result of massive thrombosis or hemorrhage

On the basis of information contained in this protocol we can merely state that this patient died of a sudden increase of pressure in the right hemisphere most likely as a result of massive edema secondary to ischemia produced by vascular occlusion.

#### Dr. Schoerer's diagnosis

Cerebral vascular occlusion of undetermined origin

Doctor Lopez: I noticed in the cerebrospinal fluid findings that the chlorides were at least in the upper limits of normal and the sugar low. That together with 90 per cent lymphocytes causes me to think that it is due to syphilis or tuberculosis. A tuberculoma is possible.

Doctor Leland: I think everything points to syphilis except the cerebrospinal fluid. Serology was negative but I do wish to call attention to the fact that a gold curve high in the middle is known as a luetic curve in the old classification.

### PATHOLOGIC FINDINGS

Doctor Fust: I would like to thank Major Schaerer for trying to make a silk purse out of a sow's ear. We are all perfectly aware that it is difficult if not impossible to put a finger on the precise cause of death in this patient. I think only one who has seen such a case would be able to include it in a differential diagnosis and even then not with any great degree of certainty. Aside from severe pulmonary congestion and edema and the little bit of atherosclerosis that was generalized, the significant findings were in the brain. The gyri and sulci of the cerebral hemisphere were found to be a little more flattened than those on the other side. You can see in the area of the internal capsule (fig. 1) this large defect made up mainly of abscesses which range in diameter from 0.5 to 3.0 cm.

Cavitation occurs somewhat posterior to the area you have just seen (fig. 2). The abscesses contained grayish brown or bright yellow necrotic material. Microscopically a polymorphonuclear leukocytic reaction is seen at the centers of the necrosis. Somewhat peripheral to this are areas of chronic inflammation mainly centered around small blood vessels. There are giant cells in the pus usually near or around nonseptate hyphae (fig. 3A). When we say nonseptate we mean that you can look along this tube (fig. 3B) and see no divisions. This is a characteristic of the family Mucoraceae which is made up of several genera including mucor and rhizopus both of which are thought to cause disease in man probably with recently increasing frequency. We cannot distinguish between rhizopus and mucor in the tissue but we can culturally. Mucormycosis as a disease of man usually involves the lungs or central nervous system. Some of the cases appear to have been caused by species of mucor others by species of rhizopus. We

*Figure 1 Abscesses in the right cerebral hemisphere*

*Figure 2 Cavitation in the cerebral abscess.*

may call the disease mucormycosis in either event because of the familial name

Figure 3 (A) Multinucleated giant cells engulfing fungi ( $\times 400$ ) (B) No septate Mucoraceae ( $\times 600$ )

Bauer and associates<sup>1</sup> described 2 cases of mucormycosis and collected 9 others. Of these, 6 certainly had diabetes, 1 had hemochromatosis, and 1 was a possible diabetic. There is a triad of symptoms in the majority of cases but as is true of most clinicopathologic conferences, not in this case. The triad includes ophthalmoplegia, evidence of meningoencephalitis, and diabetes mellitus. Bauer and associates thought that the sinuses are the point of entry in cerebral cases. The organisms are sometimes called "sugar fungi" because of their ability to break down carbohydrates, and Garrett<sup>2</sup> was quoted as saying

The fungi have the peculiar ability to invade apparently healthy arteries with subsequent arteritis and thrombosis. The most significant pulmonary lesion is actually infarction due to thromboarteritis. There is no mention of it in the protocol of this autopsy but many of the cranial cases have had extensive thrombosis of internal carotid arteries in addition to the smaller areas of arteritis within the brain. This is in keeping with Major Schaerer's idea that thrombosis with subsequent cerebral edema occurred in this case. Figure 4A shows such an inflamed artery with thickened wall and incipient thrombus. I cannot see any organisms here but chances are that with other stains they would be apparent in the arterial wall.

Figure 4B demonstrates a vessel in which there is a giant cell that almost surely indicates that there are organisms within this vessel. The fact that only a few such cases have been reported does not mean that this is as uncommon. I have seen two unreported cases and there have probably been many unrecognized ones. There will be more. If you want to remember the classical case think of someone with ophthalmoplegia, diabetes mellitus, and symptoms of meningoencephalitis. You cannot do much for him. You can give him iodides and treat his diabetes. Those who have the cerebral form of the disease die. Apparently others who have had diabetes and the pulmonary form of the disease have recovered with control of the diabetes.

# ACCURACY OF PREDICTION OF MILITARY SUCCESS OR FAILURE

## A Follow Up Study

ROBERT L. WILLIAMS, Major USAF (MC)

ISAIAH M. ZIMMERMAN, First Lieutenant USAF (MSC)

**M**ANPOWER IS a word that has become significant for most Americans. In this technological age, manpower, particularly skilled manpower, is one of our most important national resources. Social or economic planning today requires an assessment not only of time, money, natural resources, but also of the "human factors." The armed services, which even in peacetime constitute one of our large industries, have the continuing task of recruiting, training, and utilizing great numbers of men and women in a wide variety of jobs. The United States Air Force, in this age of jet aircraft, guided missiles, and nuclear warfare, has an unusually large demand for skilled manpower.

Each generation has had its own selection techniques for choosing men for its specific tasks. The expansion in industrial activity which began with World War II has created a demand for increasingly precise selection procedures. In the past, selection often depended on such factors as trade or guild affiliation, social status, or physical prowess. The industrial complex of today requires many technicians to manage its controls. A keen analysis of the skills of each potential recruit is needed. Waste in terms of maladaptation to the job is increasingly costly. Vast sums are spent on recruiting.

Various devices have been used in recent years to select manpower. Screening efforts probably reached their peak during World War II when as many as 40 per cent<sup>2</sup> of the potential inductees for the armed services were declared unsuitable for psychiatric or psychological reasons. The project to be discussed in this article is an evaluation of one of the familiar manpower screening procedures.

---

Presented on 16 May 1957 at the meeting of the American Psychiatric Association in Chicago III.

From Office of The Surgeon General, Department of the Air Force, Washington 25 D. C.

The rapid rebuild up of the Air Force which began with the Korean hostilities revived an urgent requirement for the screening and selection of large numbers of men for combat and combat support. This need appeared to be more critical than during World War II because of the technological advances that had occurred in the interim. Although much had been written about screening during the years of World War II there appeared to be no clear cut answers as to the effectiveness of previous efforts. For that reason the evaluation project to be described in this article was undertaken.

### SCREENING OPERATION

During the period under study the typical Air Force recruit was subjected to an analysis as follows:

He was examined physically and given an enlistment screening test designed to evaluate his learning ability. He was queried as to a possible criminal record. The Armed Forces Qualification Test (AFQT) was administered to estimate his intelligence and adaptability level. At the basic training center a second supplementary physical examination was performed, and he was also tested with a job aptitude battery. During this "processing" there was no formal psychiatric evaluation except that which might have occurred during the physical examination if the suspicions of the examiner were aroused by the recruit's behavior or statements.

In 1953 a new two step operation was inserted into the training program in order to fill the need for an evaluation process designed for prediction of psychological suitability.

The first step was a paper and pencil personal history test containing some 30 "open end" queries as to personal interests and dislikes, forced choice questions and phrases requiring completion. Certain of these items were "weighted" as to their diagnostic "clue" value. If the recruit responded to four or more of these "suspicious" items he was referred to the Mental Hygiene Consultation Unit for a psychiatric evaluation.

The Mental Hygiene Consultation Unit served as the second step of this screening operation. The Unit was situated in a building within the basic training area. It was staffed by psychiatrists, social workers and psychologists. Recruits referred through the medium of the personal history questionnaire received standard psychiatric work ups including interviews with the psychiatric social worker, projective tests and one or more interviews with a psychiatrist. This second phase of the operation was necessarily limited in time by the 11 week basic training period.

At some point during evaluation, the Consultation Unit psychiatrist assigned an "S" profile number to the trainee under the Armed Forces physical profiling system, commonly referred to as "PUMPS." The S category refers to the psychiatric profile. Designation of an S-1 or S-2 amounted to a prediction that the recruit would remain psychiatrically fit for military duty. An S-3 or S-4 profile indicated that as the result of both steps of this screening operation, a recruit was considered to have a personality disorder which would be likely to incapacitate him for effective performance of military duties.

### ASSUMPTIONS

It was assumed, from common experience, that a certain percentage of airmen would fail to meet the standards of performance required of them. Experience had also shown that most of the failures in performance usually manifest themselves in the initial phase of training. A certain number of recruits were definitely disqualified and destined for discharge. Another group was fully qualified and likely to succeed, success being defined as retention in the service during the period of study, which in most cases was about six months. A third group was assumed to exist which was "probably qualified" for success under the same standard. The latter borderline group was regarded as capable of succeeding if given brief supportive psychotherapy. All three groups were presumed to be identifiable by means of the two phase screening effort, i.e., the personal history report and the Consultation Unit psychiatric evaluation. Each man was labeled a 1, 2, 3, or 4 under the S of the profile system.

### METHODOLOGY

The setting for the study was a large Air Force basic military training center. For the purpose of this study the first 341 airmen who were given the profile S-3 or S-4 as a result of the two step psychiatric evaluation constituted the project group. The label of an S-3 or S-4 profile indicated that these airmen were expected to fail in military service because of psychological unsuitability. To evaluate these predictions, each one of these men was "tagged" and followed for the next several months.

A control group of individuals labeled S-1 was selected and matched to the project group. This matching included the selection of a "running mate" for each projectee from the same training group, from a similar geographic area, and of the same relative level of intelligence. The military history of each member of the two groups was investigated. Every airman was followed for the purposes of this study for at least four months. Some earmarked early in the study were followed for nine months. Thus, each airman in the two groups was observed within these vari-

ing periods of time after completion of basic training. His commander was queried as to whether the subject had remained on duty and if not, what disposition had been made. If he had remained on duty, a statement about his effectiveness was requested. The commanders queried were told that the evaluation was merely a routine spot check on the careers of a random sample of airmen. No reference was made to the S profile.

It should be noted that the majority of the project group was composed of individuals with character disorders hence their disposition was the responsibility of the line commanders and they were not handled by medical disposition. The commander could and often did disregard the predictions of the psychiatrist. Frequently the man had to demonstrate his disorder by non effectiveness or by antisocial behavior before any action was taken. This in part accounts for the varying periods of time during which the predicted failures "survived" on active duty. Throughout the study an attempt was made to insulate psychiatric prediction from disposition decision.

#### FINDINGS

In the project group (fig 1), 154 men (45.1 per cent) were discharged at the basic training center or at the next base, were absent without leave (AWOL) or confined at the time of the study.

Figure 1 Performance and duty status of the project group (with S 3 S 4 labels) of 341 men.

In addition, 62 men (18.1 per cent) were rated as fair or poor performers by their commanders at their permanent duty station. Thus, 63.2 per cent of the project group could be labeled for confirmed or potential failures. Only 105 men (30.7 per cent) remained on duty and were rated as satisfactory by their commanders. The fate of 20 men (6.1 per cent) is unknown. Contrasting with the control group (fig. 2). In the control group, 33 (8.7 per cent) were discharged, or AWOL, or confirmed failures.

Figure 2 Performance and duty status of the control group (with S-1 labels) of 341 airmen

men (18.5 per cent) were rated as fair or poor performers at their next base. Thus a total of 27.2 per cent could be considered failures or potential failures. It should be noted that the percentage of confirmed failures (i.e., discharged) in the control group was 8.7 per cent. Thus in the control group, 224 men (65.7 per cent) remained on duty and were rated as satisfactory in performance.

Hospitalization during the basic training period also presented a contrast (fig. 3). Fifty-three men in the project group were hospitalized in comparison with 15 men from the control group. In terms of costs, project group men cost 1,412 day

in periods of time under was queried duty and if not, was remained on duty, as requested. The command was merely a routine of duty. No ref

It should be noted composed of individual disposition was that they were not handled could and often did trust. Frequently the effectiveness or by taken. This in part which the predicted out the study an action from disposition

In the project project charted at the base absent without leave

Figure 1 Performance

Figure 4 Cost in administratively discharging men of project and control groups

### DISCUSSION

Considering the attrition and/or malfunction rate of both groups, it appears that the prediction of success or failure in military duty as indicated by the S profile was a reasonably accurate forecast. In regard to discharges alone, the project group predictions were correct roughly 6 times out of 10. The control group predictions were correct some 9 times out of 10.

Any conclusions suggested by those findings must necessarily be tempered by the limitations of the setting and by the methodology employed in the evaluation and follow up. The population was small. However, certain questions can be raised. Is a correct prediction of 6 out of 10, as in the project group, efficient enough considering the current manpower pool? What would it cost to raise the successful predictions to 7 out of 10, or 8 out of 10?

It is of interest to note that a fairly conventional psychiatric screening procedure (based on the usual notions of mental health or illness) correlated well with the military administrative "pass or fail" index, utilizing performance as the sole measure. Thus the psychiatric screening procedure is presumably justified because by its use the costly delay in eventual administrative detection of failures is reduced.

It is believed that this small project might be expanded to include a follow up of the rejectees who are released to the civilian community—doubtless to be screened again by industry. Perhaps through some benign method of cataloging the occupational fate of these men the recurring recruiting and training cycle might be unclogged to the advantage of the individual and his technological world.

### SUMMARY

It was assumed that recruits could be tested for "success," "potential success," and "non-success." The standard for non-success was simply discharge from the Air Force. The hypothesis was that by employing a fairly conventional psychiatric screening process (in an abbreviated form under given conditions) it would be possible to predict which men would stay in the ranks and which men would be discharged within six months of reporting on active duty. The study was performed at a large Air Force basic training base. A project group of 341 men was selected as "bound to be unsuccessful" (i.e., discharged). A control group was created of 341 men matched to the project group for characteristics like age, participation in same training unit, marital status, hometown area, et cetera. These two groups were followed at the basic training center and at the next duty station. Throughout the study the decision making on prediction was carefully insulated from the decision making on discharge. The findings were that the psychiatric predictions of "discharge" or "no discharge" were valid to a degree larger than obtainable by chance.

# USE OF THE MEMBRANE FILTER FOR POTABLE WATER IN THE AIR FORCE

THOMAS C. JONES, Major USAF (MSc)

**T**HE PRODUCTION of potable water under field or combat conditions has always been a problem of major importance to military commanders. Quality of a water supply as well as quantity have been essential to prevent a breakdown of functions at a critical or inopportune moment. "Tactical missions cannot succeed unless troops have enough safe water. Water is even more important than food. Untreated or improperly treated water almost always contains enough disease organisms to make it dangerous to drink. The health of the entire command is in the hands of the water purification equipment operators. They must know their job and do it right."

The United States Armed Forces have met the challenge of providing safe water. Sand pressure filters, chlorine, and halazone tablets were used during World War II to ensure potable water. The water purification set, diatomite, 50 g p m (gallons per minute) capacity, became generally available toward the end of World War II and was used in Asia and the Pacific areas. Diatomite equipment was invaluable during the Korean campaign. These units are now standard Air Force and Army equipment for producing potable water under field conditions, at advanced air bases, isolated sites, at temporary installations, and during emergencies. Complete units are light in weight, readily transportation inside of 8 hours by 3 to 4 men, and are capable of producing up to 60,000 gallons of water per day of practically zero turbidity from almost any surface source that does not contain excessive pollutants of a chemical, salty, or oily nature. The diatomite filter was developed to provide a method that could guarantee absolutely the removal of amoebic cysts and *Schistosoma cercariae* from raw surface water sources. It does this admirably and in addition removes about 90 per cent of the bacteria. Organisms that pass through the filter are killed by chemical disinfection with chlorine.<sup>1, 2</sup>

Submitted in 1957 to the Department of Sanitary Engineering, University of North Carolina, Chapel Hill, N. C., in partial fulfillment of requirements for the degree of Master of Public Health. Maj. Jones is now assigned to Headquarters, Tactical Air Command, Langley Air Force Base, Va.

The question might well be asked how does one know the diatomite filter accomplishes all of this? The filter has been time tested in the field and bacteriologic analyses have been made of the finished water that bear out the claims made for this unit. In many remote or isolated field situations however no bacteriologic laboratory has been available for water quality control. Quality control has been largely of a chemical and physical nature consisting of water reconnaissance surveys, coagulation, filtration and territorial chlorine disinfection. The lack of a light compact and rugged portable laboratory for determining the coliform index of field water supplies has been recognized by medical service preventive medicine personnel and field operators. This problem was largely solved on 31 January 1957 when the Air Force authorized lower echelons to procure membrane molecular filter portable laboratories for field use.<sup>2</sup> It is anticipated that with the portable membrane filter kit available for quality control, water of a quality commensurate with approved municipal supplies will be processed and delivered in the field.

### THE NEED FOR FIELD WATER LABORATORIES

Responsibility for a safe water supply under field conditions is a command responsibility. The Installation Engineers are responsible for the supervision and accomplishment of all work entailed in providing a safe and adequate supply. The Medical Service is charged with the responsibility for conducting investigations to determine the suitability of a supply from the standpoint of health preservation; this in turn requires surveys of sources, treatment measures, collection and analysis of water samples and interpretation of results. The services of a sanitary engineer should be utilized for the evaluation of water supplies whenever possible.<sup>3</sup>

Water for military supplies may be obtained from several types of water sources. Under combat or field conditions and at advance bases it is necessary to use any source that is available. Often this consists of highly turbid and contaminated surface sources such as were encountered in Korea. Providing a safe water in quantity places a great responsibility on the installation engineering noncommissioned officer in charge of the water point. Medical service preventive medicine personnel share this responsibility because on them rests the decision of passing on the quality of the water supplied to all personnel at the forward area. History shows that this responsibility was not taken lightly in World War II and Korea as shown by the low incidence of water borne disease outbreaks that occurred during these conflicts.

In spite of this excellent record control of water quality in the field to a great extent has depended on chemical disinfection.

tion. This was caused in many instances by the lack of adequate laboratory facilities and refrigeration, due to distance, inadequate transportation, the time factor, and in some instances enemy interference. It is a military maxim to regard all water as unsafe until proved otherwise, in other words when in doubt, "don't hesitate, chlorinate."

In situations such as those described above, the portable membrane filter laboratory kit, now available to the Armed Forces, would have been invaluable.

### DESCRIPTION OF THE MEMBRANE FILTER

The membranes used in this technique are basically different from ordinary cellulose filter paper and other types of filtering materials. They consist of a highly porous gel of complex cellulose ester polymers. The membranes have a thickness of about 150  $\mu$  (0.006 inch) and a porosity of 80 to 85 per cent. Under a differential pressure of 70 cm of mercury at 21°C they permit a flow rate of 70 to 80 ml of distilled water per minute through each square centimeter of exposed surface. A 17 mm disk has an effective surface filtering area of 9.6 square centimeters.<sup>4</sup>

Available commercially, the membrane filters vary in size from 0.5 to 9 inch disks and with pore openings varying from extremely small 10  $m\mu$  for virus studies up to 5  $\mu$  for particle sizing using air filtration. A satisfactory filter disk for field use consists of the 47 mm diameter and 0.5  $\mu$  pore size filter disks for use in the field are available with imprinted grids on the surface to facilitate counting. The grid subdivides the surface area so each square represents 1.0 per cent of the effective filtering area.<sup>4</sup>

Portable field laboratory equipment used with the membrane filter disk consists of a 500 ml stainless steel funnel, a stainless steel filter holder (used to support the delicate membrane disk), stainless steel or Pyrex suction flask, clamps, thermometer, valves, suction pump, flaming lamp, stamp collector's forceps for handling membrane disk, small scissors, distilled water, an incubator, and a vacuum bottle or an incubator vest. The equipment listed plus necessary media and supplemental reagents come in the packaged field kit weighing between 26 and 30 pounds.<sup>1-7</sup>

The evaluation of bacterial concentrations in water by means of the membrane filter technique involve five principal steps: (1) separation of the bacteria and other suspended matter from the water sample, and their collection on the upper surface of the membrane filter disk, (2) impregnation of the disk with nutrient liquid from a prefabricated pad to provide for total or differential culturing of bacterial colonies, (3) incubation of the membrane

filter and nutrient pad assembly (4) counting and evaluation of the types of bacterial colonies and (5) preservation of the membrane filter disk as a permanent record.<sup>4</sup> The assembly of the apparatus and the filtering of the water after the sample has been collected can be accomplished almost as quickly as it takes to tell about it.

### LABORATORY CONTROL OF MILITARY WATER SUPPLIES

The Armed Forces place great emphasis on bacteriologic examination of water consumed by personnel on military installations and under military jurisdiction. Laboratory examinations of water samples are essential to the maintenance of the quality of the water in accordance with established standards of potability. They provide a measuring stick for determining the quality of water drawn and the effectiveness of different treatment units. They also serve as a guide for adjusting water treatment processes.<sup>5</sup>

Another requirement for military water supplies at fixed installations requires that samples should reach the laboratory within 12 hours after collection whenever possible.<sup>6</sup> This is sometimes difficult of accomplishment and in field situations often impossible.

Military water samples are examined in accordance with accepted procedures,<sup>7</sup> and consist of the standard 3 dilution 5 tube most probable number (MPN) determinations of coliform density. To process water samples using MPN determinations requires a well equipped laboratory, highly trained technicians, and considerable time—at least 48 hours if only the presumptive test is run. It is quite evident that under field conditions the collection, icing (if possible), and shipping of water samples when laboratories are available is quite a chore. Results often are not received for a week or more and are too late to do much good especially if the water point has been moved to a new location.

The MPN method of bacteriologic water analysis has been in use for a considerable period of time while the membrane filter method for all practical purposes is comparatively new, having been introduced into the United States from Europe in 1947.

The adoption of membrane filters in Germany during World War II was brought on largely by the exigencies resulting from mass bombings and the shortage of trained laboratory personnel. With glassware shattered and incubators at a premium health departments of several cities such as Hamburg and Stuttgart found true economies of equipment and labor in the membrane filter procedure.<sup>8</sup> Since that time the technic has been evaluated by numerous investigators who have reported on membrane filter applications for many different purposes and under varied conditions. Private and state university laboratories the United

States Public Health Service, and the Army Environmental Health Laboratory have been instrumental in the continued development of membrane filter techniques.

Accuracy, reliability, cost, time of making analyses, and time involved in training technicians must be considered in evaluating the two methods. This is best done by describing the laboratory research and practical work accomplished by the various investigators studying the capabilities of the membrane filter.

#### COMPARISON OF THE MEMBRANE FILTER AND MPN METHODS IN EXAMINING SEA WATER

A comparison of the membrane filter and MPN techniques was made by Presnell Areisz and Kelly<sup>11</sup> in examining sea water. They performed carefully controlled experiments to determine the effect of bacterial densities on the agreement of results of the two methods, and the influence of turbidity on the agreement of results.

Water samples were collected from three stations selected on the basis of degree of pollution and turbidity. Stations were designated A, B, and C. Station A represented an approved shell fish producing area with an MPN per 100 ml of 70 or less, Station B represented a median area (restricted) with MPNs of 70 to 700 per 100 ml, and Station C represented a closed area with MPN exceeding 700 per 100 ml. Samples to be examined were taken twice daily and collected in accordance with standard procedures. Time elapsing between collection and beginning of examination of samples never exceeded two hours.

Included in table 1 are the comparable coliform densities obtained by membrane filter and MPN methods using the 95 per cent confidence limit of recorded MPNs as a base line.

TABLE 1 *A comparison of coliform densities in sea water as determined by membrane filter and MPN methods<sup>11</sup>*

Station	Average turbidity p p m.	Number of samples	Number of samples agreeing	Number of samples disagreeing	Per cent agreement
A	8	46	36	10	78.3
B	20	45	37	8	82.3
C	14	48	48	0	100.0
All stations	14	139	121	18	87.1

Summarizing the results of this experiment, it may be said that

- 1 The two techniques gave results 87 per cent in agreement
- 2 Results obtained from waters having high coliform counts gave better correlation than results obtained from low coliform density waters
- 3 Water turbidity greatly influenced the coliform recovery rate and should be considered in conjunction with bacterial density in determining the volume of sample to be filtered

4 Presnell and associates concluded their report by stating "The time and material saving features of the membrane filter method as compared with the MPN technique make it particularly desirable for examining the frequently large number of samples required for determining sanitary quality of water in shellfish producing areas."

### TIME AND COST FACTORS

Renn found that "the separate operations of preparing quantitative liquid media for MPN estimations of bacteria and the business of washing up glassware after each run was consuming roughly 40 per cent of the working time." In short he estimated that the bacteriologist on the project was reduced to a half time bacteriologist. With the adoption of the membrane filter method of bacteriologic analysis the limitation on the bacteriologist's production rate was set by the time spent in counting membranes. The time required for preparing samples and time for cleanup was reduced to insignificant levels. This resulted in a great saving of time and money.

The experience gained with the membrane filter in experimental studies led to its adoption at the Johns Hopkins University for class laboratory use. The student groups were made up largely of young civil engineers, none of whom were especially good laboratory technicians. The membrane filter was particularly well suited for use by these students as the techniques of working with it were easily learned and resulted in a saving of time.

An interesting secondary use of the membrane filter technique is the preparation of permanent records of critical experiments. Demonstrations of results can be made by placing the dried preserved membranes in transparent plastic folders mounted on Bristol board or other suitable material.

The preservation and mounting of membranes for permanent records of water samples is shown in figure 1. This is a reproduction of a preserved membrane, with sheer colonies easily apparent. Pertinent data regarding the water sample is recorded in the space below the membrane.

*Figure 1 Example of permanent records using membrane filter disk as part of potable water report*

This type of record occupies little space, is inexpensive, graphic, and easily understandable. It will be of great benefit to military preventive medicine personnel and field water plant equipment operators. A record such as this should be especially valuable as a timesaver, eliminating the need for computing MPNs and writing out rather detailed (and often misunderstood) reports.

#### ADVANTAGES AND DISADVANTAGES OF THE MEMBRANE FILTER RELATIVE TO MPN METHODS

##### Advantages of the Membrane Filter Relative to MPN Methods

1. One of the principal advantages of the membrane filter is that with its adoption by the Armed Forces, a portable membrane filter bacteriologic laboratory is now available for water sample analysis at water points located in isolated areas, whereas so often in the past, no method of determining water quality has been available other than by chemical and physical methods.

2 Eliasson stated "Precision has been achieved far beyond that conceivable by any other method of coliform analysis" <sup>11</sup> "It is desirable to keep in mind the fact that, unless a large number of portions of sample are examined the precision of the fermentation tube test is rather low. For example, even when the sample contains 1 coliform organism per ml about 37 per cent of 1 ml tubes may be expected to yield negative results, because of irregular distribution of the bacteria in the sample. When 5 tubes with 1 ml sample in each are employed under these conditions a completely negative result may be expected less than 1 per cent of the time."

"Even when 5 fermentation tubes are employed however the precision of the result obtained is not of a high order. Consequently, great caution must be exercised when interpreting in terms of sanitary significance the coliform results obtained from the use of a few tubes with each dilution of sample."

3 Results are obtained in a relatively short period of time. "It has been variously estimated that between 40 and 50 per cent of the time used for running MPN determinations is used for the preparation of media and washing up. Less labor per sample is required for the membrane filter technique. Labor in today's laboratories is a major factor in cost" <sup>10</sup> The greater productivity of existing (laboratory) personnel makes the membrane filter technique even more attractive <sup>11</sup> <sup>12</sup>

4 The membrane filter lends itself to field use. The portable kits permit "on site" filtration and incubation of water samples within a few minutes. The samples if incubation is not available can be filtered and the membrane filter disk shipped to a laboratory on a preservative medium at ambient temperatures. Results of this method have proved satisfactory <sup>10</sup> <sup>11</sup> <sup>12</sup>

5 Greater reliability is achieved by securing actual bacterial numbers at the sampling site rather than after growth or die off during transit to the laboratory <sup>13</sup>

6 Another factor which gives the membrane filter an advantage is its versatility. It can be used for many other purposes other than for water sampling. Not the least of these is the fact that it can be used as an air sampling device <sup>14</sup> <sup>15</sup> This will be covered in subsequent discussions in more detail.

7 Space is of paramount importance whether it be under field or laboratory conditions. The membrane filter meets the requirements of space and weight satisfactorily, the field kit being no larger than an ordinary suitcase and weighing approximately 30 pounds complete.

8 Preservation of membrane filter disks as a graphic compact method of retaining permanent results of water sample analyses is a major advantage. The disks preserved and mounted on suit

able material tell a picture story. Individuals totally unfamiliar with bacteriology can inspect visually and quickly be made to understand the significance of colonies growing on a membrane filter whereas trying to explain the same results reported from MPN data is extremely difficult, not to say impossible.

9 Training military preventive medicine and laboratory technicians and specialists in membrane filter techniques will require less time and equipment than similar training involving MPN determinations.

#### Disadvantages of the Membrane Filter Relative to MPN Methods

1 The coliform density estimates obtained using the membrane filter technique are generally less than the MPN method. The difference in density estimates is partly but not wholly the result of the mathematical bias of MPN. There is also some question as to whether the same organisms are counted in the two tests. More study is needed.<sup>10</sup>

2 In waters containing unusually large amounts of algae, clogging of membranes may preclude testing large enough samples to provide a reliable indication of coliform density.

3 In highly turbid waters filter clogging may limit usefulness.

4 Variations in skill of individuals in recognizing and distinguishing the characteristic sheen colonies may cause variations in results.

5 Cost of membrane filter disks are greater in comparison than the costs of media required for "negative" fermentation tube tests. This is narrowed when a good many tests require confirmation or completion. The cost of membranes should go down as they come into more common use.<sup>10</sup>

#### OTHER USES OF THE MEMBRANE FILTER

Among the advantages listed for the membrane filter was one concerning versatility. Experimenters have worked on, and are presently engaged in research on applications of the membrane filter technique in air pollution studies, evaluating air cleaners, isolation and identification of microorganisms in food and dairy products, collection of radioactive and fluorescent particles for detection purposes, isolation and identification of biological pathogens, analysis of sewage and industrial wastes and many other areas.

*Microbiologic air pollution* Goetz<sup>16</sup> discussed a specific method for the collection of microbiologic air contaminants which employs an initial conversion of the airborne matter into a liquid suspension in the presence of protective colloids by an impingement process, followed by further concentration and subsequent nutrition on molecular filter membranes.

*Size determination of silica particles* Burke<sup>17</sup> discussed the sampling of silica dusts by means of the membrane filter. The dust was collected on a membrane filter, the filter dissolved by means of an organic solvent and dust particle size determined by turbidimetric methods. The method was adjudged reliable and rapid.

*Use of the membrane filter in the measurement of biological incorporation of radioactive isotopes* Atkinson and McAdden stated "The estimation of total isotope incorporation into metabolizing cells is often necessary. In such cases direct counting of radiation from the intact cells will generally be desirable. The main requirement for accuracy is removal of radioisotopes external to cells and uniform plating of a suitable thin layer of cells."<sup>18</sup>

The membrane filter was found suitable for the collection of samples for counting. The time required was less than other methods since the cells were retained quantitatively on rather than in the filter. Absorption of radiation by filter was found to be negligible.

*Dairy products* Rodriguez and Walter<sup>1</sup> described the use of the membrane filter in evaluating dairy products consisting of butter, ice cream mix and ice cream. Their findings indicate that under laboratory conditions the membrane filter portable field kit produced results comparable to those obtained employing standard methods. They justified its use for the microbiologic rating of butter, ice cream mix and ice cream.

*Isolation of organisms from spinal fluid* Wayne and Junrez<sup>20</sup> reported their success in using membrane filter technique for isolating *Coccidioides immitis* from the spinal fluid of two patients having coccidioidal meningitis. They had been totally unable to isolate the organism from either patient by standard techniques.

#### PROPOSED AIR FORCE TRAINING PROGRAM IN THE USE OF THE MEMBRANE FILTER

It is expected that the membrane filter since its adoption by the Air Force for field use will become in the not too distant future a standard item of equipment for use by preventive medicine personnel. Air Force laboratories, water and sewage plants and other Air Force owned or operated facilities requiring laboratory analyses.

Prior to any widespread use of the membrane filter by Air Force preventive medicine personnel, laboratory personnel, or water and sewage plant operators it will be necessary to initiate a training program in the use of the membrane filter. This can be readily accomplished by including hours for training in the curricula of existing courses for preventive medicine and laboratory

technicians currently being taught at the School of Aviation Medicine, Gunter Branch, Gunter Air Force Base, Ala

Training accomplished at the School of Aviation Medicine will serve a threefold purpose (1) provide a trained corps of military personnel familiar with membrane filter techniques who will be available in the event of emergencies, (2) stimulate interest in membrane filter methods, which may result in additional research into improving existing procedures and developing new applications, and (3) eventually cause a saving in dollars and cents by the reduction in time involved in making routine laboratory water analyses based on global deployment of the Air Force

Command Surgeons can accomplish training in the use of the membrane filter for personnel unable to attend a formal training course by delegating a responsible officer, preferably the Command Sanitary and Industrial Hygiene Engineer, to initiate a training program at base level. Base clinical laboratory officers and sanitary and industrial hygiene engineering officers can serve as instructors to enlisted personnel on an "on the job training basis." In the event these officers are not familiar with membrane filter techniques, arrangements can be made with the United States Public Health Service for them to receive training at the Robert A. Taft Sanitary Engineering Center, Cincinnati, Ohio.

There is a possibility also that the manufacturers of membrane filter field kits<sup>6-7</sup> would co-operate in a training program by demonstrating and giving a familiarization short course on membrane filter applications to certain key personnel, such as the instructors in preventive medicine and clinical laboratory courses at the School of Aviation Medicine, Gunter Branch.

#### SUMMARY AND CONCLUSIONS

The lack of adequate bacteriologic water quality control under field conditions has been discussed. In the past this control was dependent on chemical and physical disinfection because of a lack of practical, portable bacteriologic laboratory equipment for water analysis. The adoption by the Air Force of the membrane filter portable field kit in January 1957 has provided preventive medicine personnel with the equipment needed to make rapid, precise analysis of field water supplies. The membrane filter was compared and evaluated against the standard MPN method of bacteriologic water analysis with the following conclusions:

1. The adoption of the membrane filter by the Air Force for use in the field was a definite step toward improving water quality control at advanced bases, isolated installations, and at field water points.

2. The increased precision over existing methods of water analysis will make the membrane filter a very useful tool for

military medical laboratories at fixed installations where routine water quality control tests are performed. Its use would result in a great saving of time, equipment, and money.

3. The adaptability and versatility of the membrano filter would make it a useful diagnostic tool in clinical laboratories, industrial plants, and other Air Force facilities requiring laboratory control.

## Uncomplicated Pregnancy Following Bilateral Lung Lobectomies

ZACHARY T. TRAVICK *Captain USAF (MC)*

ARTHUR LEBER *Captain USAF (MC)*

ARCHIBALD G. M. MARTIN III *Lieutenant Colonel USAF (MC)*

**T**HE OCCURRENCE of pregnancy following pneumonectomy is unusual inasmuch as diseases requiring pulmonary surgery are infrequent in women of childbearing age. Formerly the two most common indications for resection were bronchiectasis and certain lung abscesses. However, with the increasing list of indications for, and the decreasing mortality and morbidity following extensive pulmonary surgery, it is likely that in the future more women with pulmonary resections will become pregnant. Although this combination will present a serious problem, the outcome is not necessarily unfavorable.

### CASE REPORT

A 19-year old woman had a history of cough productive of large amounts of sputum since the age of six months at which time she was said to have had pneumonia. The cough was characteristically worse in the morning and was productive of large amounts of yellow phlegm. At times there was hemoptysis associated with episodes of chills and fever. The cough was so severe that it was necessary to raise the head of the bed at night for ease of respiration. Past history also revealed maxillary and frontal sinusitis with head colds and a drainage from the right ear. The patient had had jaundice at the age of seven years and had been hospitalized for five weeks with apparent complete recovery.

In February 1953, the patient was seen at a university hospital because of the chronic productive cough. Examination revealed scarring of the right tympanic membrane and tenderness over the right mastoid area. The tonsils were hypertrophied to grade III and were slightly injected. There was a mucopurulent postnasal discharge. Cervical adenopathy was noted bilaterally. Examination of the lungs revealed bronchial type breathing with vocal fremitus increased in, ses  
posteriorly and laterally and some generalized rales 1  
There was some clubbing of the fingers and toes. Bronch d  
bilateral lower lobe bronchiectasis. Sinus films were a 1

capacity revealed 39 33 and 39 per cent on three occasions with a total pulmonary capacity varying from 1 000 to 1 200 ml of inspired air

In March a right middle and lower lobectomy was performed Post operatively the patient did well and the hospital course was uneventful and uncomplicated Following discharge the sputum decreased in amount to less than a half cup per day There was a moderate gain in weight and no more episodes of hemoptysis The dyspnea was decreased in severity The patient returned to the university hospital in November for re evaluation At this time vital capacity was approximately 47 per cent A bronchogram showed involvement with bronchiectasis of the left lower lobe and lingular segment of the upper lobe

In November the left lower lobe and the lingular segment of the left upper lobe were resected Again the patient ran an uneventful postoperative course and two weeks postoperatively the vital capacity was found to be 1 liter or 33 per cent of normal Following the second discharge from the hospital the patient again did fairly well for many months but in the latter part of 1954 she again developed an increased amount of cough and recurrent episodes of hemoptysis and pleuritic chest pain The cough became productive of increased amounts of yellow sputum and the patient had recurrent bouts of pulmonary infection with fever and leukocytosis

The patient was first seen in the clinic of this hospital in October 1955 at which time she was found to be in about the second month of gestation This was her first pregnancy Her last menstrual period began 16 August and was of two days duration The previous menstrual period began 1 July and was of five days duration Examination revealed numerous rhonchi and coarse bubbling rales in both lung fields, slightly hyperresonant to percussion There were no areas of dullness Clubbing of the fingers was present Pelvic examination revealed a uterus enlarged to the size of a 2½-month pregnancy Fetal heart tones were not heard A roentgenogram showed the trachea to be slightly deviated to the left Both diaphragms were elevated and the costophrenic angles were blunted bilaterally A mild compensatory scoliosis to the right was present giving the cardiac shadow the appearance of lying mostly in the left lung field The left diaphragm was more elevated than usual and the supradiaphragmatic area was considerably hazy because of old pleural adhesions No active underlying lung disease could be detected An electrocardiogram was within normal limits Hemogram and urinalysis were within normal limits The serologic test for syphilis was negative The sputum was negative for acid fast bacilli The patient's blood was Type A and Rh negative A vital capacity at that time was 2 4 liters

Because of the apparent increase in vital capacity and inasmuch as the patient had no dyspnea and her health did not seem to be affected adversely the pregnancy was allowed to continue The patient was

seen at frequent intervals in the medical and the prenatal clinic thereafter. She frequently complained of chest pain, cough tightness in the chest, difficulty in bringing up secretions, and recurrent low grade infections with slight fever. However, there were no complaints of increased dyspnea. Treatment consisted of expectorants, prophylactic antibiotics, and an injection of influenza polyvalent vaccine. Roentgenograms of the chest taken at frequent intervals showed no appreciable change in the appearance of the lung fields. Three electrocardiograms showed no evidence of myocardial disease or of ischemia. No Rh antibodies were present on frequent tests throughout the pregnancy.

At about the seventh month of gestation the patient went into premature labor and spontaneously delivered a 4 pound 14 ounce living infant under local 1 per cent Novocain (brand of procaine hydrochloride) pudendal block. There was no dyspnea, cyanosis, chest pain, or other unusual symptoms. There was a moderate postpartum hemorrhage, and a transfusion of 500 ml of whole blood was required.

The immediate postpartum period was uneventful, but on the seventh postpartum day the patient developed a sudden, very severe pain of a stabbing quality in the left lower portion of her chest. She also developed dyspnea and faintness and when first seen was quite pale and complained of numbness of her arms and feet. Vital signs were not impaired. She was treated with oxygen and narcotics, and after several hours the pain disappeared. The following day a similar episode occurred and again was relieved by narcotics. Blood cell counts following this episode were always within normal limits. Daily roentgenograms revealed no evidence of pulmonary infarction or of other changes. Electrocardiograms showed no change from the previous tracings. There was no hemoptysis, fever, or leukocytosis. After the second episode the patient had no more difficulty and was discharged on the seventeenth postpartum day in good condition. The mother and infant were discharged in good condition.

The patient was seen several times during the following six months and her condition from an obstetric standpoint was normal. She continued to have recurrent bouts of pulmonary infections, however, and required frequent courses of antibiotics. Her dyspnea, weight, and general condition remained about the same as prior to pregnancy. Vital capacities were 1,500 and 1,200 ml on two occasions.

At this time bronchography, utilizing one of the rapidly eliminated opaque media, was contemplated; however, before the opaque media desired could be procured, the patient moved elsewhere.

### DISCUSSION

This case presented an interesting problem in the differential diagnosis of postpartum chest pain. First, the various forms of chest wall pain must be considered, although as a group they are not particularly increased in incidence or aggravated by

delivery or pregnancy. Intercostal neuritis is usually fairly easy to recognize and the segmental distribution of herpes zoster is characteristic. Spinal cord lesions and mechanical nerve root compression are related more specifically to coughing, sneezing and straining and other activities which increase the cerebral spinal fluid pressure. The pain of intercostal neuritis is usually lancinating with electric shock sensations and can be aggravated by stimulation of the nerve proximal to the point of pain. Muscular pain in the chest wall such as that in acute torticollis is familiar and easy to recognize. However, it is not so well known that myositis may also involve the rhomboid group of muscles and the shoulder girdle muscles at their thoracic attachments. Costochondral pain is probably much more frequent than is generally realized. This syndrome, first described by Tietze, consists of clearly localized pain in one or more of the cartilages with tenderness to pressure and usually with a palpable enlargement of the cartilaginous bridge adjacent to the lower rib. The pain is usually of a dull character with little relationship to respiration or movement and it may be quite severe. Injury to the chest wall sustained after delivery while the patient is unconscious or under the influence of narcotics and analgesics probably occurs more than we are willing to admit. Special precautions must be taken to prevent the patient from being rolled onto the grip handles of the delivery table. Finally "rheumatic" pains including fibrositis and spondylitis must be considered, although they are of infrequent occurrence in the thoracic region.

Cardiovascular pains usually occur in the older age group although they are not by any means unheard of in the childbearing age. Most frequent of these perhaps is myocardial infarction. The characteristic substernal pain with radiation into the left shoulder is easy to recognize. The diagnosis is confirmed by the increased white blood cell count, sedimentation rate and the characteristic electrocardiographic picture. Pericarditis occurs very frequently in the younger age group and may be difficult to distinguish from other types of cardiovascular diseases. The presence of a friction rub together with a characteristic electrocardiographic pattern however is usually present. Aortic pain is becoming increasingly infrequent and usually occurs only in older age groups. The diagnosis of this disease may be very difficult unless the possibility is kept in mind. The pain is described as a deep boring agonizing type pain comparable to a severe toothache. It is either retrosternal or may be posteriorly located when an aneurysm exerts pressure on the thoracic spine. Other symptoms arising from pressure and encroachment of the aneurysm also may be present.

Abdominal diseases are well known to cause referred pain in the chest. Probably the most frequent of these, and one which might occur in the childbearing age, is the splenic flexure syn-

drone. This diagnosis unfortunately must be made only after other organic causes of similar pain have been eliminated by thorough studies. Gallbladder disease may cause referred pain in the right shoulder and, occasionally, in the left shoulder and other areas of the chest. Other characteristic signs and symptoms of gallbladder disease, however, are usually present. Subdiaphragmatic conditions, with hemorrhage or infection in the reproductive organs, may be associated with pregnancy and delivery.

Mediastinal diseases and those not involving the parietal pleura and pericardium may exert referred pain to the chest wall and may indicate serious intrathoracic disease. The pain is described as a vague, indefinite sense of distress in the region of the pathologic process, and diagnosis may be very difficult.

The most common causes of chest pain in the childbearing age, and which would be associated with pregnancy and delivery, are those diseases causing irritation of the parietal pleura. The most common of these, of course, is pneumonia. This diagnosis immediately comes to the mind of all who see patients with thoracic pain and the characteristic rales, friction rub, cough, expectoration, and elevated white blood cell count, and roentgenographic findings usually make the diagnosis simple. Pneumonia occurs more frequently following delivery because of decreased defensive mechanisms against disease and because of aspiration of secretions associated with anesthesia. Pulmonary embolism is not uncommonly associated with delivery. This disease produces a characteristic pleurisy associated usually with hemoptysis, and if the embolus is of sufficient size, with a characteristic plaque like appearance on roentgenographic examination within a day or two. There is also a leukocytosis and elevated sedimentation rate. Activation of a pulmonary tuberculous process is increased during pregnancy and may manifest itself only after delivery. The roentgenographic appearance usually explains the cause of the pain immediately. Malignant diseases may be increased during pregnancy because of the influence of the great alteration in sex hormones.

Lastly, there must be considered the pleural pain caused by pulling of adhesions on the parietal pleura associated with the sudden decrease in intra abdominal mass and the sudden lowering of the diaphragm. This process is not discussed to any extent in the literature, but it apparently is not infrequent in patients who have had previous pulmonary disease and have developed pleural adhesions. It is largely a diagnosis of exclusion and should be made only after the previously discussed causes of pleural pain have been eliminated. There is no roentgenographic change, leukocytosis, or increase in sedimentation rate. I believe that our patient experienced this type of pain.

## COMMENTS

No other case of pregnancy with such extensive pulmonary resection is found in the literature. As has been pointed out before, the degree of function following resection depends not so much on the amount of lung left as upon the age of the patient and the excellence of function of the chest wall and of the diaphragm.<sup>1</sup> It is well known that the load of pregnancy causes an increased oxygen requirement, increased blood volume, and increased work of the heart. Long and associates,<sup>2</sup> however, reported a case of pregnancy following a right pneumonectomy for adenocarcinoma in which there was no significant change in the ventilatory portion of the respiratory function. Wright,<sup>3</sup> Pitheu,<sup>4</sup> and Kellerman and Smith<sup>5</sup> reported other cases in which there was no subjective increase in dyspnea during gestation. Thus, in none of the five above mentioned cases was there any evidence that pulmonary capacity is impaired by pregnancy, and indeed, in three of the cases there was a slight subjective improvement. Thomson and Cohen<sup>6</sup> suggested that vital capacity increases slightly as pregnancy advances and the subcostal angle widens, but there is probably an additional mechanism in effect following resection. There is always a degree of compensatory emphysema following removal of lung tissues and the enlarging uterus probably aids pulmonary function in the same manner as does an emphysema belt or a pneumoperitoneum. With this reasoning the danger period would be in the immediate postpartum period and such was the case in two of the deliveries. Our patient experienced pleural pain on the seventh and eighth postpartum days, probably due to tension on visceroparietal adhesions.

While therapeutic abortion can be justified in a woman following pulmonary resection, the evidence, though small, indicates that this is not always the wisest course. Many patients will desire to proceed to term and if kept under careful observation they may be allowed to do so in selected cases where no other complications are expected.

## SUMMARY

A case is presented of a patient with a right middle and lower and a left lower lobectomy and lingulectomy who had a normal uncomplicated pregnancy and a spontaneous but premature delivery. It is suggested that many selected postpneumonectomy cases may safely be allowed to proceed to term.

### COBALT 60 TELETHERAPY IN CANCER

"Cobalt 60 teletherapy is essentially a form of super voltage radiation. There is no specificity of action on the various modalities of supervoltage and it is a misconception to suppose that Co<sup>60</sup> teletherapy has something to offer when 2 million volt x ray therapy has not. Both offer the possibility of increasing the dosage of radiation to tumors because of better skin tolerance and a slight increase in tolerance of the deeper structures. But both must be used with due regard to the possible later appearance of subcutaneous and deep muscle fibrosis and other signs of cumulative damage and the curability of a tumor is one of its fundamental biological properties. *Supervoltage or Co<sup>60</sup> teletherapy is not indicated in a number of conditions, e g lymphomas in areas of superficial lymph nodes. Its use is elective in a number of other conditions e g, mediastinal and retroperitoneal lymphomas. Its use is imperative in a considerable number of conditions including cancers of the oropharynx and urinary bladder and late cancers of the cervix and vagina. It has technical advantages that need to be explored further but an objective and unemotional approach is necessary.*"

# Generalized Skin Eruption Caused by Bromsulphalein

DAVID L. DEUTSCH *Lieutenant Colonel, MC USA*

OTTO W. NEUBUERGER *Captain, MC USAR*

OSWALD R. JENSEN *Colonel MC USA*

THE Bromsulphalein (brand of sulfobromophthalein sodium) excretion test has become one of the most acceptable and valid of those used for determination of liver function. When one compares the number of times the test has been used and the relative paucity of published reports on its adverse effects it becomes apparent that it is a relatively very safe procedure. More important of course, are the occasions of adverse reactions observed by physicians which are never written up for publication or dissemination. In our own experience, and from communications with others it would appear that except for an occasional local irritation from extravasation of the drug the incidence of any generalized manifestation from Bromsulphalein has been nonexistent or very rare.

An acute allergic reaction in a patient with a history of bronchial asthma and who exhibited severe sensitivity reactions to many substances was reported by Chambers and Moister.<sup>1</sup> The reaction was evidenced by severe dyspnea, cyanosis, unconsciousness and clonic convulsions. De Andino and McKeown<sup>2</sup> observed a case characterized by dyspnea, cyanosis, apprehension and hypotension which appeared within three minutes after injection of the drug. Anaphylactoid reactions also were noted by DiCaprio and Troen,<sup>3</sup> Roth and Morey, Gabuzda and Scudamore and McVay. Morey and associates reported two cases of mild local inflammatory reaction.

We have found no previous reports of generalized severe coalescing morbilliform rash resulting from the intravenous injection of Bromsulphalein as manifested in the following case report.

## CASE REPORT

A 44-year-old soldier was undergoing study for jaundice of four days duration associated with vague diffuse abdominal pain and anorexia. Physical examination findings were not remarkable except

---

From Ireland Army Hospital, Fort A. 17

for obvious jaundice and a slightly palpable nontender liver. Liver function tests showed a total bilirubin of 5.8 mg per 100 ml, with direct bilirubin of 3.1 mg and an indirect 2.7 mg per 100 ml. Thymol turbidity was 2.6 units. Serum alkaline phosphatase was 16 Shinowara-Reinhardt, Jones units. At this time a Bromsulphalein excretion test was performed using a total of 370 mg of dye (5 mg per kilogram of body weight) injected intravenously. Within about 1 hour the patient developed a nonpruritic, finely macular, generalized rash of the entire body except the palms and soles (fig. 1). Over the next several hours

Figure 1 The macular coalescing rash involved the entire body except palms and soles

the rash became more intense, began to coalesce and continued to do so for several days. Also noted was a temperature of 103°F which subsided in 1 day while the rash increased in intensity and after several days also subsided. Complete clearance of the rash took about 5 to 6 days. There were no clinical manifestations of other diseases in which a morbilliform rash is seen. Blood cultures, roentgenogram of the chest and heterophile antibodies were all negative. The jaundice subsided in 2 weeks. The initial Bromsulphalein re

tention was 67 per cent at 45 minutes. No further injection was given but a skin test utilizing 1 ml of 1:10,000 Bromsulphalein and patch test using 1:20 concentration were both negative. A punch biopsy from the right leg showed aggregates of chronic inflammatory cells in the upper dermis interpreted as dermatitis consistent with dermatitis medicamentosa. Gallbladder series showed cholelithiasis for which the patient underwent cholecystectomy uneventfully at a later date. He gave no history of any previous allergic manifestations and had never been exposed to Bromsulphalein previously.

### SUMMARY

A case of generalized severe coalescing morbilliform rash caused by intravenous injection of Bromsulphalein is reported.

# Hindquarter Amputation for Hip Chondrosarcoma

EARL W. BRANNON *Lieutenant Colonel USAF (MC)*  
JOHN I. TRACY *Major USAF (MC)*

**T**HE PURPOSE of this article is to describe an interesting case of chondrosarcoma of the hip apparently arising from a pre-existing synovial chondromatosis and to evaluate some of the more practical points concerned in the management of such a patient on whom a hindquarter amputation is to be performed.

Billroth attempted the first hindquarter or interinnominate-bdominal amputation 67 years ago, however, the patient died shortly after the operation, probably from shock. In 1895 Girard achieved the first successful hindquarter amputation, which consists of removing the entire lower extremity with the adjacent innominate bone. The principles of the surgical procedure were laid down by the English surgeon, Hognrth Pringle,<sup>1,2</sup> in 1909 when he reported three cases.

There are over 185 recorded cases to date, most of which have been performed for sarcoma. Prior to 1934 the operative mortality for this procedure was about 60 per cent. Since then the mortality has been less than 20 per cent, and the improvement may be attributable to the use of transfusions and better supportive measures. American surgeons did not gain interest in the operation until after 1940. In 1942 Loughton<sup>3</sup> reviewed the literature and reported three of his own cases. He pointed out that shock and prolonged suppuration were the chief causes of early death. Morton<sup>4</sup> reported four cases in which the amputation was done primarily as a palliative measure. He stressed the necessity for careful hemostasis and the avoidance of surgical shock. In England, Gordon-Taylor and co-workers<sup>5,6</sup> had the most outstanding experience in this field with over 21 personal cases in which their operative recovery was a commendable 71 per cent. The final prognosis was most favorable in the infiltrating chondroma or chondrosarcoma, some of their patients being free from recurrence nearly 10 years after amputation. Interestingly,

most of their amputations were performed under spinal anesthesia and with the patient in a true lateral position. Gordon Taylor and co-workers emphasized the need of a retention catheter during and after the operation and the importance of having adequate blood supplies at hand. In 1946 Pack and Ehrlich<sup>7</sup> reported six cases of amputation for malignant tumors. They believed that the radical procedure served a distinctly useful role in the treatment of selected patients.

Beck and Bickel reported 12 cases in their series from the Mayo Clinic. When the hip is primarily involved pain may be severe and the tumor may be small and hard to demonstrate as it was in our case. All of their cases had a temporary respite from pain. In 1949 Ariel and Hark<sup>8</sup> reported eight cases and emphasis was placed on utilizing this procedure with dispatch when indicated. During the same year, Wise<sup>9</sup> reported his experiences with hindquarter amputation in five patients with primary malignant tumor of the innominate bone or upper part of the thigh. There was no operative mortality in his series. Saint<sup>10</sup> reported a case of osteosarcoma of the innominate bone treated by amputation about four months after the appearance of the tumor. The patient subsequently died a short time thereafter. Saint emphasized the necessity of early diagnosis of malignant disease if adequate removal of the tumor is to be successful and his article contains an excellent discussion of the operative management. Coley, Higinbotham and Romieu<sup>11</sup> reported a series of 14 cases, 3 of which were osteogenic sarcoma and 11 chondrosarcoma. They believed that the rather long term palliation made the procedure definitely worthwhile. Necrosis of the skin flap and persistent sinus with residual abscess were the most frequent complications encountered. Coley and his associates believed that chondrosarcomata of the hip and pelvic bone were secondary sarcomatous evolutions of benign chondromas.

Despite early failures, the procedure has gained more recognition in recent years with a present mortality rate of approximately 15 per cent. Modern anesthesia, blood restitution and antibiotics have greatly extended the field of this extensive type surgery. The indications for such a radical operation will always be limited. Most of the procedures have been done for malignant tumors affecting the proximal portion of the thigh, hip or innominate bone so that removal by hip joint disarticulation was impossible. The prognosis will depend on the anatomic type and extent of the tumor, the number of recurrences prior to surgical intervention and the presence of distant metastases. The procedure should not be withheld from any patient whose only chance of survival lies in its performance.

## CASE REPORT

A 34 year old Air Force pilot was admitted to this hospital 24 October 1955 complaining of pain and stiffness in the right hip. In December 1954, he spontaneously developed pain in the hip region. There was no antecedent history of injury. Pain persisted for three weeks after which he reported to his local base hospital where a diagnosis of arthritis of the hip was made and an extensive course of physical therapy, including diathermy, given. The pain became more intense with further limitation of motion and the patient was transferred to another hospital. Roentgenograms of the hip at this time revealed no evidence of bone or joint disease. On 31 March 1955, arthrotomy of the joint was performed with partial excision of the synovium and anterior capsule. Clinical impression substantiated by the pathologist's reports was synovial chondromatosis. The wound healed uneventfully and after a course of physical therapy, the officer was discharged to duty 21 April. Upon return to flying status, he served a period of temporary duty in North Africa and again developed pain and stiffness in the involved hip to the extent that he could no longer fly.

Evaluation at his local base hospital 15 October revealed virtual ankylosis of the hip with severe pain upon weight bearing, and roentgenograms showed periparticular amorphous calcification about the hip joint (fig. 1). In the 10-month period following initial onset of symptoms the patient had lost 15 to 20 pounds even though his appetite remained good. He was referred to this hospital for hip fusion. Past history was noncontributory with no episode of specific trauma nor infectious disease process relative to the hip.

Physical examination revealed a well developed and well nourished male in no acute distress except when attempting to bear weight on the right hip. He could not walk unsupported without intense pain in the hip joint. The head, neck, upper extremities, chest, and abdomen showed no significant findings. He stood with the pelvis tilted forward on the right and a compensatory lordosis and scoliosis of the lumbar region. A 20° flexion contracture was present in the right hip with no demonstrable flexion, extension, abduction, adduction or rotation movements. Spasm of the adductor musculature was present with 1-inch atrophy of the thigh and 1½ inch atrophy of the calf. A well healed, nontender 8 inch surgical scar was present over the anterior aspect of the right hip with a 2 cm nontender mass palpable beneath the upper aspect of the old scar. Neurologic examination was negative, and circulation in the right lower extremity normal.

Admission laboratory work revealed a normal blood count and urinalysis. The sedimentation rate was elevated to 35 mm. The blood alkaline phosphatase was reported as 7.4 iu/l and Armstrong units. A roentgenogram of the chest was negative. A roentgenogram of the right hip revealed a large amount of granular calcareous debris within

and about the joint and demineralization of the head and neck of the femur (fig. 1) Review of roentgenograms taken March 1955 showed no significant findings relative to the involved hip

*Figure 1 Roentigenogram October 1955 showing granular calcareous material within and about right hip joint with demineralization of head and neck of femur*

Initial clinical impression was a recurrence of the pre-existing synovial chondromatosis. The patient was placed at bed rest in traction for relief of pain. In view of the virtual ankylosis of the hip and severe pain upon attempted motion and weight bearing, it was believed that another arthrotomy and joint cleansing procedure should be performed.

On 14 November 1955 a posterior approach to the hip was made with excision of diseased synovium and adjacent tissues with a large amount of soft friable and calcareous material. The head and neck of the femur and the acetabulum did not appear to be involved. The mass present in the upper part of the old incision was also excised. The patient was kept in bed with balanced suspension while the wound healed.

The local pathologist's report was chondrosarcoma, both of the tissues removed from the hip joint and the mass from the old incision. The sections revealed neoplastic cartilage with marked pleomorphism of the nuclei, pyknotic nuclei and marked variation in size of the

nuclei (fig. 2). The nests of cartilaginous tissue were separated by dense fibrous connective tissue. The impression of chondrosarcoma was later confirmed by the Armed Forces Institute of Pathology, Washington D. C. In view of these findings, the case was presented to the hospital tumor board which concurred with the recommendation that a hindquarter amputation be performed as the only possible treatment for the relief and/or eradication of this disease.

Figure 2 Biopsy specimen showing characteristics of chondrosarcoma. Note the binucleate cartilage cells and large hyperchromatic nuclei ( $\times 264$ ).

The patient finally submitted to surgical intervention 29 December when the entire right lower extremity with the adjacent innominate bone was removed through the sacroiliac and pubic joints. The procedure was performed under general hypotensive anesthesia with the patient in the lateral position and the operating time was 100 minutes. The anterior and posterior portions of the dissection were carried out simultaneously

with two tubes and the operative technique described by King and Seelquist<sup>11</sup> was essentially followed. Two tissue drains were laid in the extraperitoneal space and brought out at each end of the wound after closure of the posterior flap (fig. 3). A Foley catheter was in place during the operation and connected to a tidal drainage system after return to the recovery ward. The patient tolerated the extensive procedure without event, having been surprised with a transfusion of

Figure 3. Postoperative photograph showing placement of a flap and tissue drains.

2,500 ml of blood. At the time of surgery he required an extension about the incision and through the operative incision and he felt that there were distinct ripples in the old posterior and anterior scars (figs. 4 and 5).

The recuperative course was smooth except for the usual postoperative pain in the sternal area. Tetracycline sodium was used to control bowel movements during the first 24-hour period after which oral administration was resumed. The drains were removed 48 hours postoperatively and there were even until wound healing was assured. Except for a small superficial operative area in the superior part of the flap the wound healed well. This area was later connected by anastomosing an abdominal flap. Two weeks after the operation, the patient was up and about on crutches and undergoing rehabilitation in physical therapy (figs. 6 and 7). His appetite was good and he had no interference with bladder or bowel function. He had considerable relief of the previous pain.

Figure 4 Neoplastic cartilaginous cells with interspersed fibrous tissue (x 60)

Figure 5 Nest of malignant cells exhibiting pleomorphism. The cartilaginous tissue shows marked pleomorphism (x 100)

The patient went home on convalescent leave and did well until 3 April 1956 when a roentgenogram of the chest first revealed evidence of pulmonary metastases. During the next two months he developed progressively intense pain in the pelvis, right sided headaches and some discomfort in the chest upon deep inspiration. He developed haziness of vision in his right eye and palpable nodules in the right portion of his scalp. Roentgenograms in July revealed destruction of the sacrum and both lung fields were heavily infiltrated with snowball metastases. He ran a rapidly downhill course with progression of symptoms relative to the pelvis, chest, right eye and scalp during

Figures 6 and 7 The healed posterior flap two months after amputation

which period the intense pain was controlled with spinal injections of absolute alcohol, heavy opiates and inhalation of Trilene (brand of trichloroethylene). The patient lapsed into a semicomatose condition and died during sleep 26 August, some 20 months after initial onset of symptoms.

The final clinical diagnosis was chondrosarcoma of the right hip, probably secondary to synovial chondromatosis.

Autopsy was performed 26 August and the gross anatomical findings were: (1) chondrosarcoma of right hip with extensive metastases; (2) pulmonary chondrosarcomatosis with metastatic chondrosarcoma of ribs; (3) epidural metastatic chondrosarcoma, spinal and cranial; and (4) metastatic chondrosarcoma to the tissues between the scalp and skull.

#### DISCUSSION

Unfortunately, there was a time lapse of some 12 months between the onset of symptoms and hindquarter amputation in this

case. Although the initial diagnosis was a carcinoma of the colon, there may be a question of extent of the disease. At the same time, certainly it is essential to know the extent of the disease before it can be carried out as a curative procedure. For survival if the lesion is beyond the bounds of resection and if it is not resectable, roentgenographically of course.

It is well known that the physical and psychological treatment have been attempted to relieve by various means. It is not feasible to perform this in the long run alone. Case reports from the literature have been reported with a variety of prostheses may be found in the literature. Our patient was not able to undergo amputation with a healthy colon. It is a lead a virtually normal and a good evidence of a good pre-operative condition after operation.

The technique of operation is described and the following points are mentioned. Psychologic preparation of the patient for extensive procedure is essential. Before operation the bowel is prepared with pre-operative cleansing enema and a tube is inserted. A Foley catheter is connected to a urinary bag. The procedure is carried out under general anesthesia. A transfusion is started before the operation to minimize the risk of shock. The patient is placed in the lateral position and supported. A little rotation is required to perform the dissection. Anesthesia with induced hypotension was found to be a factor in our case and the length of operation was considerably with two surgeons performing the anterior and posterior dissections simultaneously. However, it should be mentioned that with good supportive treatment and good anesthesia there is no great necessity for a hastily performed procedure and the possibility of rough handling of tissues and subsequent wound complications.

A large posterior flap was fashioned without the retention of the gluteus maximus muscle, since it was thought that this muscle was possibly involved by disease. The flap healed well and there was no problem of herniation of the unsupported abdominal

viscera Tissue drains left at either end of the incision were removed in 48 hours and postoperative Wagonston suction was instituted to relieve bowel distention Oral feeding and ambulation of the patient was encouraged as soon as possible Systemic antibiotics were continued until wound healing was assured

### SUMMARY

A case of chondrosarcoma of the hip with hindquarter amputation is presented, together with a survey of the literature The important points in the operative technic and the management of the patient are discussed Even though this extensive operation is performed in the hope of a cure, we believe that it is justifiable as a palliative measure alone

# Thoughts on the Ellis-van Creveld Syndrome

## Report of an Analogous Case

RONALD A. MAIT Lieutenant MC USNR

**F**OR A SYNDROME to deserve a place in medical terminology, it must usefully correlate a set of anatomic, etiologic, or functional phenomena. Grouping together as a nosological entity independent variables that occur simultaneously only by chance serves no purpose. It is well, therefore, to review an established syndrome occasionally and affirm its right to a distinctive name. The appearance in our clinic of a girl with multiple congenital anomalies has directed us to a reconsideration of the Ellis-van Creveld syndrome.

This syndrome, known also as chondroectodermal dysplasia (dwarfism, dysplasia of certain epiphyseal centers, teeth, and nails, and polydactylism), has been definitely identified in 11 patients,<sup>1-11</sup> in 9, congenital heart disease was present. Other cases have been reported,<sup>12-14</sup> but either they are not truly representative of the syndrome, or they are not described in sufficient detail to enable the diagnosis to be confirmed from the reports alone.

The earliest descriptions of the disease involved accepting heart disease as an integral part of the syndrome. Coffey,<sup>15</sup> however, pointed out that the only true distinguishing abnormalities were maldevelopment of certain epiphyseal centers, notably those of the proximal tibiae and of the carpal bones, presence of an extra digit, and shortening of the distal long bones. Gellis<sup>16</sup> expressed a point of view even further removed from that of the physicians who first described the syndrome. He did not fully accept the group of malformations as representing a valid and unique syndrome, and pointed out that the Ellis-van Creveld syndrome could represent only fortuitous occurrence of isolated developmental defects otherwise seen alone or in smaller groupings.

When we recently saw a 9 year old girl with dwarfism, bone deformities, dysplasia and aplasia of the teeth, mongoloid facies, and pseudotruncus arteriosus, we thought at first that she represented a variant of the Ellis-van Creveld syndrome. Study re-

vealed that the child was in fact a curious combination of inherited and acquired abnormalities that made her but a counterfeiter of the syndrome. Her case is reported not only for its own interest but also because it may serve as an example of the way in which inherited traits can be overlaid with defects acquired during intra uterine and extra uterine life and the resultant become known as a syndrome—if the same chain of circumstances happens by chance three times.

### CASE REPORT

The patient was born on 13 November 1947 the daughter of healthy young parents with no history of consanguinity. Prenatal development had been complicated by the appearance of progressive polyhydramnios beginning at the fifth month of gestation. Delivery was by low forceps three days after rupture of the fetal membranes.

Immediately after the child's birth the attending physician noted cyanosis, a hemangioma of the forehead and extremely short arms and legs. Inquiry revealed that a maternal aunt had short arms and that the hemangioma had been present in at least four successive generations on the maternal side of the family. There was no family history of diabetes, syphilis or of any other developmental abnormalities but there was a marked history of allergy.

From 1948 to 1951 the patient was seen annually at the Johns Hopkins Hospital by Drs. Harriet G. Guild and Helen Taussig. A diagnosis of truncus arteriosus with left aortic arch was made. Chondrodystrophy was also considered, but as follow up roentgenograms revealed no abnormality this possibility was discarded. Pertinent physical findings during those years were short stature, cyanosis and a soft blowing systolic murmur heard over the precordium. The hematocrit was 55 ml per 100 ml. Roentgenograms of the chest were compatible with the diagnosis of truncus arteriosus. Electrocardiographic findings were consistent with right ventricular hypertrophy.

Cardiac catheterization was performed in 1952 at the U S Naval Hospital Bethesda Md following consultation at this school. Because atrioventricular dissociation developed, the catheterization had to be terminated and studies are incomplete. The following data were obtained: right ventricular pressure 100/0 mm Hg, superior vena cava oxygen saturation 13.6 ml per 100 ml, right ventricle 11.4 ml per 100 ml. The truncus could not be entered.

Angiocardiography demonstrated flow of the contrast medium from right atrium to right ventricle and thence to a large truncus. Some contrast medium flowed from the right ventricle into the lung fields perhaps signifying a small pulmonary artery. Large retroesophageal collateral bronchial arteries were demonstrable. The questionable presence of a pulmonary artery resulted in a change of diagnosis to that of pseudotruncus arteriosus.

Multiple dental extractions were performed in 1954 for relief of caries and periapical granulomata and abscesses

The patient was examined for the second time at this school in 1956. She was 9 years old and in the 20th centile for weight (25.2 kg, 55.5 lb) and under the 3d centile for height (120 cm, 47.2 in.). Her arms and legs were short in proportion to the trunk (fig. 1), and there was limitation of radial deviation of the wrists. The forehead was prominent, the nose broad and flat, and the epicanthal folds distinct. A large bluish capillary hemangioma was present in the middle of her

Figure 1 Photographs of the patient at nine years. Relative shortness of the forearms and clubbing are apparent. The mongoloid facies and frontal hemangioma are not so striking in the picture as they are in life.

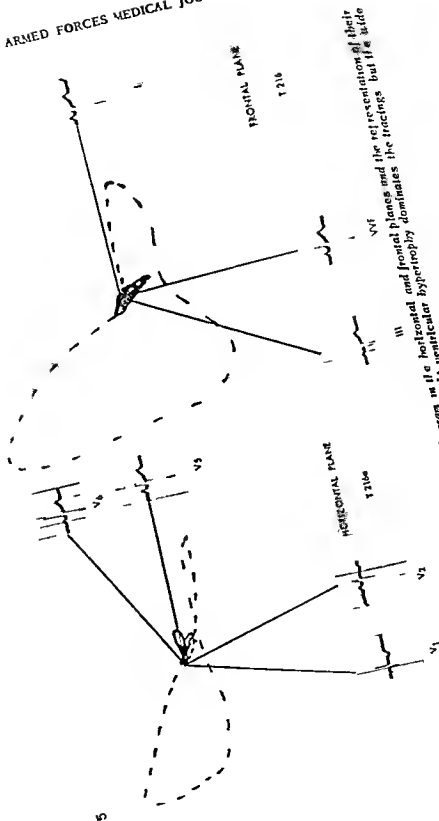

U S NAVY  
MEDICAL

Figures 2 and 3 Posteroanterior and left anterior oblique roentgenograms.  
Prominent features are the concavity in the region of the pulmonary artery  
and hypertrophy of both ventricles

ailed no abnormality. A few per-  
 use were malformed and carious  
 it appeared normal, and the thyroid

*ity of the distal radius imperfect radiocarpal artic-  
 and short bones of the forearms are characteristic*

Figures 5 and 6. Loops refer to the vectorcardiogram in the horizontal and frontal planes and the representation of their axial projections as conventional electrocardiograms. Right ventricular hypertrophy dominates the tracings but the axial angle is clearly seen in the horizontal plane.

Roentgenograms for cardiac configuration (figs. 2 and 3) showed the presence of right and left ventricular hypertrophy and retroesophageal blood vessels. A concavity was present in the region of the pulmonary artery; no "shelf" was seen in the left anterior oblique view. Pulmonary vascular markings were slightly less prominent than normal. Full mouth films showed the absence of buds for both upper lateral incisors. All other teeth were present but most were unerupted. Roentgenograms of the forearm were diagnostic of Madelung's deformity (fig. 4). Other long bones were not abnormal. The bone age was about 6½ years.

Conventional electrocardiograms were indicative of right ventricular and atrial hypertrophy. The loop representing the vectorcardiogram was a classical example of findings in right ventricular hypertrophy (figs. 5 and 6).

On the Stanford-Binet scale the IQ was 102.

### COMMENTS

The clearly inherited traits in this case are the frontal hemanjioma and Madelung's deformity. The relation of the hemanjioma to the rest of the patient's disease is ill defined. Madelung's deformity has been shown to be a dominant characteristic,<sup>16</sup> in this case, the patient's maternal grandfather probably also had the deformity. On this background of heredity is superimposed a pattern of delayed growth secondary to congenital cyanotic heart disease, yielding in combination the picture of a malformed dwarf.

The contribution of intra uterine life to the composition was pseudotruncus arteriosus. Whether a primarily blighted ovum evoked polyhydramnios, or whether a maternal abnormality manifested by polyhydramnios resulted in congenital heart disease is a matter for conjecture.

Between these two rather definite extremes of nature and nurture lies the ectodermal dysplasia. In its most obvious form, ectodermal dysplasia results in absence of many teeth, deformity of those present, maldeveloped fingernails and hair, and defects in the growth of the facial bones, for the most part the disease is sporadic. In this case, the dysplasia is in evidence by absence of two toothbuds, alleged defect in the quality of the enamel of the deciduous teeth and perhaps, in association with a mesodermal defect, also by the broad flat nose, prominent forehead, and epicanthal folds suggesting mongolism.

Comparison of this case with examples of the Ellis van Creveld syndrome reveals some obvious parallels. Each has a well known hereditary component—in one case, Madelung's deformity, in the other, polydactylism. Each has a factor of sporadic occurrence—namely, ectodermal dysplasia. Each has a form of dwarf-

ism. In our case the dwarfism is probably subsequent to life long hypoparathyroidism, in the Ellis van Creveld syndrome its etiology is not known but it is likely that it is related to the epiphyseal dysplasia. The congenital heart disease common to the two diseases is both statistically and inductively a product of intra uterine existence.

As a result of these comparisons it seems that Cellis' view of the Ellis van Creveld syndrome has much merit. The syndrome could be explained by chance occurrence of unrelated factors as in our case. On the other hand, the unique skeletal deformities delineated by Caffey are constant phenomena in the well documented cases of the syndrome and there is some evidence that a recessive gene is responsible for the chondroectodermal dysplasia. Thus if a syndrome does exist, it seems logical to restrict the definitive characteristics to lesions of bone, and perhaps also of ectoderm as Caffey has done, and place the element of congenital heart disease in the background.

## SUMMARY

The case of a 9 year old girl with dwarfism, Madelung's deformity, partial ectodermal dysplasia, and pseudotruncus arteriosus is presented to show how genetically determined traits were intermixed with acquired traits to yield the final clinical picture. Comparison is made with cases of the Ellis van Creveld syndrome. Certain similarities which are noted lead to the proposal that the definitive manifestations of chondroectodermal dysplasia and that the congenital heart disease usually present be regarded merely as an accessory abnormality.

#### NATURAL HISTORY OF HERPES ZOSTER

"The course of herpes zoster was studied in a series of 206 patients that included infants and octogenarians. There were 32 patients under the age of 20 in 30 of these (94 per cent) the condition cleared up in 14 days or less. The infection was more severe and prolonged in older patients. In four elderly patients symptoms persisted six months or longer. The relative frequency with which the various parts of the nervous system were involved varied from youth to old age. No instance of involvement of the ophthalmic division of the trigeminal nerve was observed in patients under the age of 20 but ocular complications did not appear to be related to the aging process. Post herpetic neuralgia did not occur in patients under 20 but was frequent in patients over 50. Sex race and season did not perceptibly influence the incidence of infection in this series."

## Departments

### A MESSAGE FROM THE A M A

In its present form, Asian influenza, caused by a new virus mutant, is only temporarily disabling. Even so, it could strike enough military personnel to cause serious disorganization in our military departments, at least on a short term basis. Service sent specimens of the virus from the Far East last April to the Walter Reed Army Research Center in Washington, D C, for typing. More recently, with indications of a probable epidemic outbreak of the disease in this country, a determination was made to vaccinate military personnel, since the disease is highly contagious and spreads very rapidly. Arrangements have been made with the manufacturers of the vaccine to earmark part of their output for military use.

The American Medical Association, in co-operation with the Public Health Service, has launched a nation wide preparedness program to combat an outbreak of Asian influenza among the civilian population in this country. The A M A Board of Trustees, in July, designated its Committee on Civil Defense, Council on National Defense, as a Special Committee on Influenza to implement a program of action designed to mobilize medical manpower and institute other precautionary measures to cope with any influenza outbreak this fall and winter.

The A M A program consists of an informational and an operational phase. The informational phase got under way on 26 July, when packets of material on Asian flu were sent to members of the A M A House of Delegates, presidents of state medical societies, secretaries of county medical societies, and chairmen of state emergency medical service committees. National allied health and medical associations have been urged to assist and co-operate and to ask their constituent bodies to join with local medical societies in formulating plans for co-operative efforts.

For the past two months, a series of articles has been published in the *Journal of the American Medical Association* covering historical and scientific aspects of the disease, together with reported and confirmed incidence rates being tabulated by the Public Health Service. Articles have also appeared in

From the Council on National Defense of the American Medical Association. The views and opinions expressed are not necessarily those of the Department of Defense.

—Editor

*Today's Health* provides information as to what the general public should expect and what to do. If and when the epidemic becomes nation wide in scope, A M A representatives will be put on network television and radio programs to provide the public with information on home care and precautionary measures.

In its operational program, the Association has informed state and county medical societies of the possible impact of an influenza epidemic on normal professional services and facilities. The Special Committee on Influenza has continued to urge local medical societies to develop adequate stand by programs and plans to cope with the problem. State emergency medical service committees have been alerted to institute precautionary measures and to see that proper organizational plans are coordinated and readied in each state medical society. The Committee suggested that consideration should be given to expanded professional care through the utilization of all physicians, regardless of type of practice. Local plans should include mobilization of other professional resources, such as nurses, nurses' aides, pharmacists, and others. Action to make full use of hospital facilities should be explored, such as curtailment of elective surgery and diagnostic studies. It is essential that state and local programs be closely coordinated with public health agencies and state and local health departments.

The Committee has been particularly impressed with the prompt attention and serious consideration which this problem is receiving at state and county levels. Within three weeks after the Association pledged its support and participation in a plan to alert the nation's practicing physicians to the dangers of a possible influenza outbreak, many state and county medical societies reported the programs they had set up and the enthusiastic response which was being given by individual physician members.

Dr. David B. Allman, A M A President, Atlantic City, at the time the program was instituted said, "The epidemic may not strike in this country, but the American Medical Association is anxious to have practicing physicians mobilized and alerted in case an outbreak does occur. Thousands of persons have been stricken with the disease in the Far East, and it is only good medicine to deal in probabilities now, when we have the time. In that way, the American people will be best served from a medical standpoint."

## AMERICAN PUBLIC HEALTH ASSOCIATION TO MEET IN CLEVELAND

The 85th annual meeting of the American Public Health Association and meetings of some 40 related organizations will be held in the Cleveland Public Auditorium, Cleveland, Ohio, from 11 to 15 November 1957. In addition to the presentation of a large number of papers, there will be many technical exhibits. This year's APHA meeting will include many research reports on subjects related to the maintenance of a healthful environment and an aggressive attack on disease and disability. Of about 400 scientific papers to be presented in 75 sessions, more than half will concern research accomplishments or opportunities.

Considerable interest will center around a session on radiation protection which is scheduled for Wednesday morning. The session will include a symposium on current status in setting radiation exposure standards, a scientific paper on community health problems due to peacetime uses of radiation to be presented by Roy J. Morton, associate director of the radioactive waste disposal research project at Oak Ridge National Laboratory, and president-elect of the association, and a paper on program planning for radiation protection to be presented by Dr. Herman E. Hilleboe, New York State health commissioner, and Alexander Rahm, Jr., chief of the radiological health section of the New York State Department of Health.

Another session of timely interest will be a panel discussion on influenza including epidemiology, status of vaccine production and utilization, control measures, and laboratory services. This session is scheduled for Thursday morning.

Other topics will include health implications of new food and milk processes including use of chemicals and antibiotics, freezing and irradiation, the effects of housing quality on morbidity, food implications of changes in the American pattern of diet, and developments in mental health including school and community programs and new programs for retarded children.

There also will be discussion of new research implications for detection and measurement of air pollution, developments in sanitary control of drinking fountains, home swimming pools, hotels, motels, and tourist homes, and technical developments in fluoridation including experience in maintaining constant fluoride concentrations and possibilities for fluoridating individual water supplies.

The problems of habituating drugs in industry development and testing of new chemicals to combat cancer statistical studies on perinatal mortality, prematurity, and the epidemiology of cancer and other diseases, and new patterns of medical care programs in hospitals and elsewhere will be covered

Four general sessions are scheduled On Monday morning, prominent national leaders will take part in a symposium on public policy aspects of public health planning Tuesday evening's session will feature addresses by the Association's president, Dr John W. Nutson, assistant surgeon general and chief dental officer of the U S Public Health Service, and Dr Lowell J. Reed, president emeritus of Johns Hopkins University The Sedgwick Memorial Medal will be presented at this session Lasker Awards of the American Public Health Association for 1957 will be presented Thursday evening A closing symposium Friday afternoon will focus on public health priorities for 1958

## REHABILITATION AND EMPLOYMENT OF THE PHYSICALLY HANDICAPPED

Members of the Armed Forces of The President's Council on Handicapped, which will be observed during 6 to 12 October. President Eisenhower evinces his concern for the employment

have a special interest in the activities of the Council on Employment of the Physically Handicapped. The following message from President Eisenhower expresses his concern for the furtherance of such efforts.

There is one basic thing to remember about the physically handicapped. It is good business for the person. It makes no sense to be relatively helpless. I understand this and am helping workers

employment of workers who are physically handicapped. It is good business for the nation and good for the individual. I like to congratulate the citizens who would otherwise be unemployed and who are now employed.

Now we must tell others about the physically handicapped because two million Americans are still waiting to be used. Two million Americans could enter the labor force today if they were properly prepared.

the value of employing the physically handicapped. Americans with physical handicaps are still waiting to be used. Americans could enter the labor force today if they were properly prepared.

I urge all employers to employ the physically handicapped wherever possible. I urge all workers to accept the physically handicapped as their coworkers. In these demanding times the cooperation of our nation is our most precious asset. Working together the handicapped can add spirit and power to America as we seek to improve the standard of living for the world.

## SIX MEDICAL CORPS OFFICERS SELECTED FOR GENERAL OFFICER AND FLAG RANKS

Five Army and Air Force Medical Corps officers holding important professional assignments have been promoted recently to general officer and a Navy captain has been selected for rear admiral. The new Army general officers are Brigadier Generals Thomas J. Hartford, MC USA, deputy commanding general of Walter Reed Army Medical Center; James C. Forsee, deputy commanding general of Walter Reed Army Hospital; and Carl W. Tempel, commanding general of Valley

Brown, director of the staff in the office of Assistant Secretary of Defense Frank B. Berry, and John K. Cullen, director of plans and hospitals in the office of Major General Dan C. Ogle, surgeon general of the Air Force.

## Reviews of Recent Books

**WORLD-ATLAS OF EPIDEMIC DISEASES, Part III, First of four issues,** edited by Professor Dr med Ernst Rodewaldt and Privatdozent Dr med habil Helmut J Juxatz Heidelberg, under the sponsorship of the Heidelberger Akademie Der Wissenschaften 36 pages 10 colored maps in hard back binder, 15 $\frac{1}{2}$  by 19 inches in size, loose-leaf with three brass screw posts, of size suitable for insertion of forthcoming second, third and fourth issues Volk-Verlag, Hamburg 1 Germany, 1957 Price DM 75, plus extra charge for postage and packing

This first issue of Part III of this world atlas provides continuation of the geomedical presentation of epidemic diseases. Parts I and II have been reviewed in previous issues of the *U S Armed Forces Medical Journal*. This volume contains descriptive sections and color maps pertaining to the following topics: brucellosis in Europe, rabies, schistosomiasis in Africa, plague, leishmaniasis and filariasis in the Americas, yellow fever and schistosomiasis in South America. Also included are recent (1949-1954) data on the composition and distribution of populations in South and Central America.

In these days of rapid global travel these atlases provide a valuable addition to the literature on geomedicine. Differing from those books which provide the reader a summary of all diseases of importance in a particular area or country, the approach of the atlas is to present a more detailed description of a single disease on a continental or multicontinental basis. Notable features in relation to the zoonoses are the tabulations and distribution mapping of potential animal hosts and vectors with adequate reference to sources of information.

The descriptive summaries are concise and defined within the span of years. As witnessed by the section on yellow fever in South and Central America, the summaries are accurate and up-to-date for the defined period. In the case of dynamic diseases, however, even a few years bring many changes and it is hoped that supplements will keep the information as current in future years as it is now. These atlases are a must for the military medical library, the medical school, health departments concerned with international travel and as a source of reference for all others who are concerned with geomedicine.

—JOHN P SEAL, CAP, MC US.

**RHEUMATIC DISEASES, RHEUMATISM AND ARTHRITIS,** by Kenneth G Brugsch M D, F A C P 330 pages illustrated J B Lippincott Co, Philadelphia, Pa, 1957 Price \$10

This monograph describes the anatomic physiology, physical examination, diagnostic procedures, and treatment of rheumatic conditions.

A separate chapter is devoted to laboratory procedures but whether this should be included in such a volume or left to a text on laboratory procedures is debatable

The author has included a separate chapter on treatment as well as a section on the therapy of each clinical entity presented To this reviewer this appears to be reduplication There is a chapter for each of the commonly classified rheumatic diseases each of these entities is presented in comprehensive sequence One does not find psychogenic rheumatism as a clinical entity The author has included a worthwhile chapter under the heading of "Diseases Simulating Rheumatic Diseases" Side effects of therapeutic agents are discussed and the more common features presented This chapter might have been expanded further

References are listed at the end of each chapter Some of the more recent works such as Rammelkamp's on rheumatic fever have been omitted The text is easily readable well indexed and adequately illustrated Although the format of this volume is a little unusual it is a worthwhile text and reference book

by Jack R Ewalt M D Edward A  
and Franklin G Ebaugh M D 8th

**PRACTICAL CLINICAL PSYCHIATRY**  
Strecke M D Sc D LL D The Blakiston Division McGraw-Hill Book Co Inc  
edition 457 pages New York N Y 1957 Price \$8

This is the eighth revision of a textbook first published by Strecke and Ebaugh in 1925 The major part of the present revision apparently was done by Dr Ewalt It has a new format and is a larger book bulk wise than the seventh edition however it contains less material and is larger primarily by virtue of the fact that this edition is printed on thicker paper The book is divided into three sections including seven chapters on "Basic Concepts" 17 chapters on "Clinical Syndromes" and 13 chapters on "Treatment" Chapter 12 Mental Deficiency was written by Malcolm J Farrell M D and chapter 24 Child Psychiatry and Mental Health Practices was written by Warren T Vaughan Jr M D The new psychiatric terminology adopted by the American Psychiatric Association and the American Medical Association is used throughout

For the most part the subject matter presented in the various chapters is of good quality and informative particularly for the beginner or the medical student This reviewer however objects to the deletion of much of the illustrative clinical material In the preface the authors stated that because of the increase of clinical material in clinics and reaching facilities the inclusion of such descriptions in a textbook is no longer necessary It is the feeling of this reviewer however that particularly in psychiatry wherein one deals so frequently with the intangible manifestations of illness and their effect upon the personality illustrative clinical material is essential to provide information to the general practitioner medical students and the be

October 1957)

REVIEWS OF RECENT BOOKS

1515

ginner in psychiatry to assist in differentiation of the various nuances and clinical manifestations of psychiatric illness

The sections on "Basic Concepts" and on "Treatment" are particularly good and well worth reading. The clinical syndromes might have been amplified by a more detailed discussion of the character and behavior disorders that appear. This is a group of disorders which all psychiatrists have a tendency to neglect, but about which many questions arise among personnel working with social agencies, the police, child guidance groups, and public institutions. This book has much to offer, but its over all value is less than that of the previous edition despite the addition of a considerable amount of up-to-date material. It may not sustain its previous popularity in competition with other textbooks of its type.—ROY F. CLAUSS, Jr., Lt. Col. MC USA

WILLIAM HARVEY, His Life and Times, His Discoveries, His Methods  
by Louis Chauvois. Foreword by Sir Zachary Cope. 271 pages, illustrated. Philosophical Library, Inc., New York, N. Y. 1957. Price \$7.50

It is most fitting and proper that in this year, A. D. 1957, on the tercentenary of the death of William Harvey, we have an opportunity to assay his life and his works. In this compact volume, Doctor Louis Chauvois, The Laureate of the Institute and the Academy of Medicine, (Paris) and an eminent medical historian, has drawn a vivid picture of this great English physician that is unique and refreshing. While drawing deeply upon past and contemporary biographers, he has studied Harvey's immortal classic "De Motu Cordis et Sanguinis," written in Latin and first published in Frankfurt in 1628.

Writing with Gallic enthusiasm, Dr. Chauvois impresses the reader with the obstacles in Harvey's path, centuries of erroneous hypotheses and theories which he questioned and refuted by years of experiments and observations on the circulation of the blood. Harvey's burning curiosity, his perseverance, his clear thinking, noticeable even during his medical school days at Padua, are brought to light. Dr. Chauvois has well evaluated and utilized his sources of material. His opinions on Harvey's classic discovery are noteworthy, while his own are added on the subject of circulation of the blood. He has given due credit in his modest bibliography, and tells the reader when he assumes a divergent point of view.

This book will stimulate thoroughly the student of medical history into a new appreciation of the momentous impetus which Harvey gave to the advancement of science. Harvey lived into his 80th year. At 72, he allowed to be published "De Generatione Animalium" upon the urging of one of his students, saying at the time "Nature however is the best and most faithful interpreter of her own secrets, and what she presents, either more briefly or more obscurely in one department, that she explains more fully and clearly in another." Harvey was memorialized this past June in the Library of Congress Exhibit of

the Month which showed a copy of his "Complete Works published in London in 1766 and a copy of "De Motu published in Padua in 1643 All physicians should delight in this book Such an outstanding medical forebear is worthy of our attention and admiration

—PAUL V DAVIS Col USAF (MC)

PRACTICAL OTOLARYNGOLOGY by Gervais Ward McAniff M D F A  
C S F I C S 320 pages illustrated Landaberger Medical Books  
Inc 1957 Distributed by The Blakiston Division McGraw-Hill Book  
Co New York N Y Price \$7

This is an excellent text for the senior medical student the general practitioner and the specialist in aviation medicine The author has considered the difficulties encountered by the general practitioner and the reasons behind these difficulties Briefly but adequately he presents applied anatomy and physiology sufficient to permit an understanding of disease when one or both are altered Of equal importance the art of medicine is stressed as well as the science and the practice of conservatism An excellent section is devoted solely to the physical and functional examination of the ears nose and throat presented superbly because of its clarity and completeness Most errors in diagnosis are a result of incomplete examination A clear description of the recognition and treatment of those minor surgical conditions by the physician who first encounters them is presented These include polypectomy antral irrigation foreign body removal and the immediate treatment of fractured nasal bones All of the conditions requiring medical or surgical care when first seen are described in detail and in excellent fashion Thorough study of this text with its easy reading will enable the untrained in otolaryngology to treat many diseases of the ears nose and throat

This text is of immense value to the flight surgeon and should be at hand as a ready reference The youngest flight surgeon engaged in air crew effectiveness finds his greatest difficulty in the recognition and treatment of diseases of the ears nose and sinuses sometimes resulting in serious sequelae A thorough acquaintance with this text will greatly enhance the therapy of the sick flyer and preclude the serious sequelae and a high noneffective rate

—FRANK A PERRI Col USAF (MC)

CLINICAL ORTHOPAEDICS No 8 Chronic Hereditary Disease and Developmental Anomalies Anthony F DePalma Editor in Chief 337 pages illustrated J B Lippincott Co Philadelphia Pa 195 Price \$7 50

There is much thought provoking and valuable material in this volume of Clinical Orthopaedics The first section is devoted to chronic hereditary diseases and developmental anomalies with articles by 15 authors from this country and abroad orthopedists anatomists and generalists Of particular practical interest is an article by Denis Brown on planning

The second section entitled "General Orthopaedics" contains 11 articles An excellent one on hemophilic arthropathy is based on an

analysis of 117 hemophilic families and includes a discussion of the correction of resulting joint deformities. Another presents the scapulocostal syndrome as a little known entity. There are two readable discussions of the public relations aspects of a physician's life, financial and medicolegal. The other papers in this section are on various clinical subjects.

The third section on motorist injuries is Part II of the symposium begun in the preceding *Clinical Orthopaedics* Number 7. This installment deals with automobile crash injury research on reduction of injuries. The medical profession, which has long considered the automobile accident as a therapeutic problem, is rapidly coming to think of it in terms of preventive medicine, and to apply medical knowledge to all causative factors, even automobile designing. To quote Doctor McElhenny from another section of this volume: "The motor car manufacturers need top medical thinking. We need cars designed to preserve life and limb."—MILTON S. THOMPSON, Col MC USA.

**THE TREATMENT OF WOUND SHOCK.** The Wound Shock Working Party, Medical Research Council Memorandum No. 34. 39 pages. Published by Her Majesty's Stationery Office, London, England, 1957. Price 3s. 6d. oct.

This small paper backed manual of 39 pages, written by the Medical Research Council and the working party for revision of Medical Research Council War Memorandum Number 1 from the privy council of Her Majesty's government of London, England, is divided into two parts. The first part discusses the nature and assessment of wound shock, while the second part concerns treatment which includes general and specific methods. An excellent descriptive text of assessment of blood loss and shock, including different types of shock, are brought out in such a fashion that this manual becomes of great value especially for younger doctors and medical students, and as an excellent review for more experienced, practicing physicians and surgeons. The abuse and use of blood and plasma expanders is rationally presented and the underlying physiology is explained.

In part two, which deals with treatment, general and specific measures are adequately presented and specific details are brought out on choice of fluid, amount of blood, rate of transfusion, and lack of response to transfusion. A discussion on the type of anesthesia utilized and a fine discussion on postoperative care are presented. Some modifications of treatment on special types of injuries and the metabolic consequences of injuries are noted. A discussion of fat embolism and anuria due to crush syndrome and other severe injuries is very adequately explained and specific therapy is indicated. There is an excellent rapid treatise on burns and, in the appendixes, a useful section on the use of plasma substitutes. The paper concludes with an appendix on untoward reactions following transfusions and the therapy thereof. In general this is an excellent manual for quick and ready reference for the treatment of traumatic injuries either due to blunt

trauma missile trauma or burns It is highly recommended for medical students interns and residents and as a very rapid excellent reference for all practicing physicians and surgeons

—VICTOR C STRATTON Capt MC USN

PRACTICAL OFFICE GYNECOLOGY by Albert Decker M D D O G  
F A C S and Wayne H Decker M D D O G A Series of Monographs Obstetrics & Gynecology edited by Claude E Heaton M D  
388 pages 103 illustrations 19 in color F A Davis Co Phila  
delphia Pa 1956 Price \$10 50

This is a practical concise well illustrated 347 page manual dealing with all phases of office diagnosis and management of gynecologic problems Factors especially stressed are simplicity effectiveness and safety The first section deals with history taking physical examination and special office procedures Certain subjects are of necessity covered only in a cursory manner notably the section on hysterosalpingography The diagnosis and management of specific disease entities are adequately reviewed This section offers a succinct review of most of the gynecologic and treatment principles of practitioner in his office The diagnostic and treatment procedures generally are standard ones The currently acceptable principles of hormone therapy are discussed in an excellent chapter which includes a complete table of commercial preparations The importance of early cancer detection is repeatedly stressed throughout the book and one entire chapter is devoted to the diagnostic aids to this end There is a complete and extensive bibliography The volume admirably fulfills its purpose in serving primarily as a useful manual for the student and as a succinct refresher course for the practitioner The presentation is not nor is it intended to be on a level comparable with a classical standard gynecologic text —HUMBERT L RIVA Col MC USA

DISEASES OF THE NOSE THROAT AND EAR by Howard Charles Ballenger  
M D F A C S and John Jacob Ballenger B S M S M D 10th  
edition 968 pages 550 illustrations and 11 plates in color Lea &  
Febiger Philadelphia Pa 1957 Price \$17 50

This new edition has been brought up to date and many surgical techniques such as rhinoplasty and submucous resection are described in detail The section on respiratory physiology is brief but excellent In the one on sinusitis there is a complete description of the various operations upon the sinuses The section on the larynx includes Morrison's recent work on the anatomy of the recurrent laryngeal nerve and reconstructive procedures for vocal cord paralysis The description for the procedure of tracheotomy is adequate but there are too few illustrations

There is an excellent section on defects of speech which is a worthwhile addition to a book of this type The physician should have an understanding of speech defects and know when to refer patients with speech disorders for speech therapy The section on physiology of

hearing is shorter, concise and clearly understandable. The last chapter on bronchoesophagology, by Jackson, is a worthwhile adjunct.

Throughout this edition, there is a notable lack of description of the simple but commonly performed procedures, such as the treatment of nasal fractures and infraction of the middle turbinate. The section on acute diffuse otitis externa, the most common disorder of the external auditory meatus, is incomplete. Bacteriologic studies done during World War II by Senzawa, which show that the etiology of external otitis is rarely due to fungi, are not reported. Current methods of treatment of this common condition are not recorded. Despite its shortcomings, this is an excellent book for residents and specialists in otolaryngology. The lack of adequate description of simple procedures and treatment of the common disorders of the ears, nose, and throat limits its use for the general practitioner.

—RALPH L. ARALS, Lt Col USAF (MC)

**ANESTHESIOLOGY AND RELATED PROBLEMS** Conference Co-Chairmen: C. R. Stephen and F. J. deBeer. 180 pages, illustrated. *ANNALS OF THE NEW YORK ACADEMY OF SCIENCES*, Volume 66, Part 4, pages 841-1022, April 2, 1957. Editor-in-Chief, Otto V. St. Quintlock. Managing Editor, Franklin A. Furness. The New York Academy of Sciences, New York, N. Y., 1957. Price \$4.

The volume is published in the general format of a professional journal, and is divided into four major parts consisting of 16 separate articles by 24 authors.

The first part discusses geriatric anesthesia. Nutritional and hematologic factors like anemia and hypoproteineremia may be concealed and unrecognized unless specific laboratory procedures are performed. It is emphasized that hasty surgery must be avoided in the presence of uncorrected nutritional deficiencies. Cardiovascular complications are treated from the standpoint of reflex, chemical and metabolic depression of cardiac function, changes in peripheral vascular resistance, interference with venous return to the heart, acute cardiac failure, and coronary disease. Mechanical problems in the use of mechanical respirators on patients with high airway resistance and low pulmonary compliance are outlined. The choice of anesthetic drugs and methods must depend on an evaluation of the metabolic functions of each individual patient.

Part two reviews controlled respiration in anesthesia, beginning with a review of respiratory physiology and a comparison of artificial respiration with natural respiration. Effects of pressure breathing on systemic and pulmonary circulation are shown, and it is concluded that a normal individual will well tolerate controlled respiration supplied by any reasonable method. The methodology of controlled respiration is approached from the aspects of pharmacologic, mechanical, and combined methods, and a warning of the dangers in the method. The evolution of controlled respiration in anesthesia practice is traced.

and the author finds it inevitable and desirable that clinical application of controlled respiration will increase

The section on fluid and electrolyte balance in surgery begins with a discussion on the diagnosis and treatment of respiratory alkalosis. The article on fluid and electrolyte therapy in pediatric surgery contains useful tables on surface area and fluid requirements. The contribution of radioactive isotopes to the study of electrolyte balance in surgery is briefly evaluated.

The final part surveys hypotension in the operating room. The effects of some anesthetic agents on blood pressure, cardiac output, and peripheral resistance are noted. The problem of adrenocortical insufficiency during surgical anesthesia is presented. The role of the autonomic nervous system in causing circulatory reflexes resulting in hypotension is reviewed and schematically charted. The hemodynamic effects of sympathomimetic amines are charted. Protective mechanisms in shock on laboratory animals are presented.

This review of problem areas encountered by surgeons and anesthesiologists will be of value to the practitioner in his daily work and to the teacher as a discussion of four current teaching problems.

—ROBERT E. LAU, Lt Col, USAF (MC)

The Principles and Methods of PHYSICAL DIAGNOSIS. Correlation of Physical Signs with Certain Physiological and Pathological Changes in Disease. by Simon S. Leopold, M.D. with a Chapter on Sounds from the Thorax. Acoustic Principles by S. Reid Warren, Jr., Sc.D. in the 2d edition. 537 pages. 379 illustrations and 25 color plates. W.B. Saunders Co. Philadelphia, Pa. 1957. Price \$9.

The second edition of this textbook on physical diagnosis presents a completely revised and improved presentation of a book which in its first edition gained wide acceptance as a standard in this field.

This edition has been expanded from 430 to 537 pages. A chapter on the pediatric examination has been added to make the book of more general value. Another on medical history has been amplified and strengthened and the one on psychiatric concepts of human behavior including some of the recent psychiatric survey has been revised by Charts and drawings have been added to discussion of the neurologic examination to demonstrate the more common neurologic lesions and indicate the proper technique in such an examination. A number of electrocardiograms and phonocardiograms have been included which record better than words can relate the auscultatory signs of numerous cardiac abnormalities.

The number of colored illustrations have been increased and new photographs have been generously inserted throughout the book. As a result the text is even better illustrated than was the first edition. This book is recommended to the student as a standard textbook in the field of physical diagnosis.

—GEORGE M. POWELL, Col, MC USA

**CIBA FOUNDATION COLLOQUIA ON ENDOCRINOLOGY** Volume 10 Regulation and Mode of Action of Thyroid Hormones. Editors for the Ciba Foundation G. F. W. Wolstenholme D. B. F., M. A., M. B., B. Ch., and Elaine C. P. Miller A. H. & C. A. R. I. C. 311 pages, 114 illustrations. Little Brown & Co. Boston, Mass., 1957. Price \$8.50.

This book is the latest addition to the Ciba Foundation's *Colloquia on Endocrinology*. The field of thyroid physiology and pharmacology has become infinitely broader with the advent of more adequate tools for investigation. This book is an important contribution in presenting the latest concepts of thyroid physiology and pharmacology and in the discussion of these concepts the participants in this symposium are among the world's outstanding authorities on the subject. A definite attribute of the book is the excellent discussion at the conclusion of each paper.

Papers are presented concerning the nature of the thyroid hormone, possible conversion to more active principals, mechanism of action, interrelationship with other endocrine gland products, and the mechanism of control of thyroid output. The techniques of experiment used in gaining these data are described and differing points of view aired in the discussion of each paper. Clinical applications are alluded to wherever possible.

The book is most useful to those interested in research endocrinology and to those interested in thyroid physiology and pharmacology. The general internist will find it useful for reference.

—WILLIAM R. SCHILLHAMMER, M.D., MC USA

**Rypins MEDICAL LICENSURE EXAMINATIONS** Topical Summaries and Questions, edited by Walter L. Biering M.D. M.A.C.P. M.R.C.P. Edin. (Hon.) with the collaboration of a review panel. 8th edition. 964 pages. J. B. Lippincott Co., Philadelphia, Pa., 1957. Price \$10.

This is the eighth edition of this compendium of medical examination questions which in itself, is a tribute to its value and practicality. The book is divided into sections on the basic sciences and the various branches of medicine and surgery. Each section is compiled by a capable authority, who has written a summary of the salient facts in his field that covers briefly but in a logical and organized way the information usually asked by state licensing boards over the years as well as new developments which might be included. This plan seems much sounder pedagogically than a long series of questions and answers. There are questions aplenty for which the answers can be found in the epitome preceding.

Perhaps one of the most worthwhile and useful chapters gives examples of questions given. Particularly since the advent of multiple choice mechanically graded questions, the understanding of a new question format seen for the first time by a candidate in the throes of examination is often a stumbling block. Familiarity with multiple choice of facts, associated and related item lists, questions whose answers depend on previous answers, quantitative values and comparisons

cause and effect types and series of questions based on case histories is a great help before the examination room is entered

This book is excellent for its purpose and should aid the student or graduate. It is a good review for anyone

—JAMES L. TOBIN, Col USAF (MC)

The Clinical Management of VARICOSE VEINS by David Woolfolk Barrow M D with a Foreword by Arthur W. Allen M D 2d edition revised and enlarged 169 pages illustrated Paul B Hoeber Inc Medical Book Department of Harper & Brothers New York N Y 1957 Price \$6.

This well written and well illustrated small volume presents for the general practitioner and for the surgical resident most of the basic information needed relative to the diagnosis and treatment of varicose veins. The pen and ink drawings make the text easy to follow. The fact that so many of our patients in the older age group present peripheral vascular problems with increasing frequency makes this monograph a welcome addition to the physician's library

—PHILIP J. McNAMARA, Capt MC USN

ANNALS OF THE NEW YORK ACADEMY OF SCIENCES Volume 64 An 5  
Pages 735-1073 March 22 1957 Editor-in-Chief Otto V St Whitelock  
Associate Editor Franklin A. Furness \*SECOND TISSUE HOMO-  
TRANSPLANTATION CONFERENCE Conference Chairmen John  
Marquis Converse and Blair O Rogers 338 pages illustrated The  
New York Academy of Sciences New York N Y 1957 Price \$4 50

This volume deals with many facets of the homograft problem but places special emphasis on alteration of the normal host graft relationships. While the ultimate objective of the permanent survival of the homograft in the human still remains an elusive goal shrouded by the mysterious and incompletely understood sequence of events known as rejection nevertheless this volume contributes to further progress in this field. This is done in several ways: (1) Ingenious technical methods are described which have and will further facilitate investigation (2) experimental data presented shed further light on the problem (3) clinical application of some investigative results are pointed out (4) avenues for further investigative work are opened up

The many papers dealing with induction of tolerance not only in the embryo but also in the adult animal lead one to hope that this may eventually be applicable to the human. The fact that skin homografts in the human survive longer if taken from individuals closely related to the recipient and whose blood groups are the same is of importance to the clinician. The demonstration that bone marrow transplants in animals survive permanently in irradiated recipients holds great possibilities for victims of this atomic age if and when this technique is made possible in the human. This volume is recommended to all those interested in the homograft problem

—JOSEPH R. CONNELLY, Capt MC USN

**PRACTICAL GYNECOLOGY** by *Walter J. Reich M.D., J. A. C. S., F. I. C. S.*, and *Mitchell J. Nechou M.D., J. A. C. S., F. I. C. S.* 2d edition 648 pages 284 illustrations including 68 subjects in color J. B. Lippincott Co. Philadelphia, Pa., 1957 Price \$12.50

With special emphasis on office gynecology rather than upon highly specialized hospital procedures, this book admirably fulfills the needs of the general practitioner for whom it was principally designed. The subject material is presented in an unusually clear and concise manner. The "to the point" differential diagnosis of gynecologic symptoms and signs is refreshingly clear. While presenting an authoritative description of elementary and time tested methods, procedures, and treatments, full consideration is given to the newer concepts and current practices of gynecology. Each chapter is complete in its coverage of the basic subject material albeit repetitious insofar as the entire text is concerned. Placing the diagnosis and treatment of female disorders within the framework of medicine as a whole further adds to its usefulness by the general practitioner as well as the student or would be specialist.

Nine entirely new chapters have been added to this expanded second edition. There also is a new section on the diagnosis of early pregnancy, and considerable material has been incorporated in the chapter on examination of the breast. Although the chapter devoted to radiation therapy is presented in a most lucid manner, one cannot help wondering whether the authors have not overreached their goal by adding this discourse to a book devoted primarily to office type gynecologic practice. The reviewer would concede that this chapter is of extreme interest but doubts that the sketchy outline would be of any great value to a general practitioner. Current literature findings do not support the authors in their recommendation of therapeutic abortion in a patient who had previously been treated for carcinoma of the breast three years before by radical mastectomy. Eastman, Westberg, Thomas Taylor White, and the writings of others would indicate that the authors' opinion is on tenuous ground at the present time. Again, full discussion of such an important subject would be best omitted from this otherwise fine publication leaving this matter to more comprehensive major works. With the exception of these minor criticisms, this book is recommended as an authoritative reference source in the field of practical gynecology for use by the general practitioner, intern, and medical student.—EDWARD A. ZIMMERMANN Col. MC USA

**DeLee's OBSTETRICS FOR NURSES** by *M. Edward Davis M.D.*, and *Catherine E. Sheckler R.N., M.A.* with a Foreword by *Ann Kitchner* 16th edition 625 pages illustrated W. B. Saunders Co., Philadelphia, Pa., 1957 Price \$1.75

It is gratifying to note that the social and psychologic aspects of pregnancy have been pointed up, and special emphasis placed on pregnancy as a normal physiologic function. This new approach clearly demonstrates the increasingly important role the nurse is being called

upon to play and makes us realize that she must become better prepared to meet this new challenge

The hospital corpsmen who have read this text without any urging were very favorably impressed. They found it extremely interesting and easy to understand. A new interest in obstetrics seems to have been stimulated which will be encouraged since we have such a marked shortage of trained interested and properly motivated personnel to staff our obstetric units.

The illustrations are excellent throughout the book.

The inclusion of the father in the total picture with parents classes and the section on natural childbirth and rooming in emphasize again that this is a normal physiologic function not an illness and therefore is a family affair.

This book which was written primarily for student nurses is also highly recommended as a reference book for all graduate nurses especially those in the advanced clinical programs.

—CATHERINE J CRANE Lt. NC USN  
—MARCUS A GODINEZ Capt MC USN

OBSTETRICAL NURSING by Carolyn Conant Van Blarcom, R N Revised by Emma Ziegel R N B S 4th edition 855 pages illustrated The Macmillan Co New York N Y 1957 Price \$6.50

This new edition succeeds in meeting its objective "to present in a modern and comprehensive form the many recent advances in obstetrics and obstetric nursing." The format is excellent the illustrations are clear and accurate and the historical data well placed for easy reading. The book is well indexed has an excellent glossary and a good bibliography at the end of each chapter. The first half is devoted to anatomy physiology the development of the baby and birth. The chapters which follow are "The Nurse's Duties during Labor" and "Analgesia and Anesthesia." These are both approached in an up-to-the-minute manner. New drugs and types of anesthesia are carefully considered and the author has given space in pointing out advantages and disadvantages of each. One chapter is devoted to "Recent Trends in Maternity Care" and though brief it covers such programs as the emergency maternity and infant care program of the World Health Organization, midwifery and the development of complete maternity care. Part VII which presents "The Care of the Baby" is excellent. It explains in detail the normal and the premature as well as describing the latest methods in care and feeding.

This excellent textbook has been revised and almost completely rewritten hence it becomes one of the most up-to-date books for nurses during their clinical experience in obstetrics. The data presented is given in an understanding manner and should make learning an easy matter. It contains a wealth of new material and should be a valuable reference. It is recommended for the libraries of all schools of nursing.

—JOSEPHINE M GREEN Maj ANC USA

**MENTAL DEPRESSIONS AND THEIR TREATMENT** by Samuel Henry Kraines  
M D 355 pages illustrated The Macmillan Co., New York, N. Y.,  
1957 Price \$8

As far back as the records of man go, "mental depressions" have plagued the human race. Many explanations have been offered and numerous treatments suggested. When Saul, the first King of Israel, became depressed, the following explanation was given: "Now the Spirit of the Lord departed from Saul and an evil spirit from the Lord tormented him." The therapy was a form of recreation. "And whenever the evil spirit from God was upon Saul, David took the lyre and played it with his hand and Saul was refreshed and was well and the evil spirit departed from him." However, recreation as a therapy has not always been so effective. Still later the humoral theory of excessive black bile was offered and remained a popular one in centuries.

During the past 30 years the psychodynamic theory has been the most popular, and the psychoanalytical school of psychiatry the most articulate. It is refreshing to receive a book challenging the predominant concepts. However, one gets the impression from Dr. Kraines' concept that the manic-depressive depression is a result of disturbed physiologic function in the diencephalic area including the thalamus, the hypothalamus, the reticular system and the rhinencephalon is possibly overstressed that its frequent repetition does not necessarily make it true. Modern psychiatric literature certainly suggests that there is a need to call attention to the possibility that psychiatry is losing the somatopsychic approach to illness of the psyche, and this book emphasizes this approach in a very interesting, comprehensive, and effective manner.

The chapters on symptoms and diagnoses are most instructive. During the past five years spent largely at Air Force training bases, this reviewer has often felt uneasiness when "schizophrenia and reactive depression were such frequent diagnoses and very seldom challenged. Dr. Kraines has made one aware of the possibility that manic-depressive illness is still with us and has emphasized the need for considering differential diagnoses. His type of therapy seems particularly practical and should be useful in the military setting.

This book is recommended for military hospital libraries, and can be read with profit by the general medical officer as well as the specialist.—CHARLES H. WIGGINS Lt Col USAF (MC)

**LOCAL ANESTHESIA AND PAIN CONTROL IN DENTAL PRACTICE** by Leonard M. Monbetsm B S, M S D D S 299 pages, illustrated  
The C. V. Mosby Co. St. Louis Mo., 1957 Price \$8.75

This unique volume implements the author's belief that dental surgical procedures can and should be done with a complete absence of pain. It contains a wealth of information concerning not only local anesthesia and pain control but also such related subjects as sterilization procedures, office emergencies, a welcome extensive illustrated

review of trigeminal nerve anatomy and function and a chapter on the medicolegal aspects of office procedures

The various techniques of block field and infiltration are described clearly and concisely. The chemical pharmacologic and physiologic properties of each are so outlined as to permit considerable latitude in the choice of agents. Perhaps too much attention is given to the extraoral techniques of local anesthesia which apparently are but seldom used in dentistry. The author discusses the physiology of pain and its control indicating that postoperative pain is also the responsibility of the dentist. It is also his belief that painless procedures depend in great part on the patient's co-operation as influenced to a degree by his pain threshold. Of interest to dental anesthetists is the stress placed on preanesthetic medication for dental anesthesia. Considerable space is allocated to the advantages and disadvantages of various drugs. This is a field that it would seem many dentists overlook entirely. The chapter on complications and emergencies is excellent as a reference for the practicing dentist and for the student who has advanced enough to understand the terminology employed.

—ROBERT F. CORWIN Col USAF (MC)

Management of the Patient with HEADACHE by Perry S. MacNeal M D  
F A C P Bernard J. Alpers M D Sc D (Med.) F A C P and  
William R. O'Brien M D F A P A 145 pages Lea & Febiger  
Philadelphia Pa 1957 Price \$3.50

This book is a rather brief survey of the problem of headache but a number of important aspects of the subject have been omitted. A great deal of general and specific information may be gleaned from its 138 pages.

The first three chapters are devoted to mechanisms of head pain of organic, psychologic, and vascular origin respectively. The discussion of psychologic mechanisms did not strike this reviewer as being very rewarding, probably because of the inherent difficulties in presenting such material in abbreviated and simplified terms.

The major portion of the book is devoted to differential diagnosis and treatment of the various types of headache. The grouping is more or less arbitrary and a certain amount of overlapping results but this does not detract from the effectiveness of the presentation. Migraine is dealt with at considerable length and the discussion is an excellent one. In regard to the so-called "histamine cephalalgia" of Horton, the authors express the opinion that food allergy is the cause and that it can be successfully managed by the use of elimination diets. They acknowledge quite clearly however the difficulties involved in successful treatment along these lines.

An important asset of the book is its readability. It is written (for the most part) in a conversational style and is sufficiently light hearted at times to make this troublesome and rather fatiguing subject of headache a little easier to contemplate.

—HARVEY E. REITZ Capt MC USN

## New Books Received

Books received by the *U S Armed Forces Medical Journal* are acknowledged in this department. Those of greatest interest will be reviewed in a later issue.

## Military Medicine—its Mission

The medical services of our Armed Forces are authorized by law to afford medical coverage—both outpatient and inpatient—for various groups in addition to active duty personnel. In peace this phase of military medicine sometimes tends to obscure the primary mission, and it is this that I should like to examine briefly.

It seems to me that the primary mission of our military medical services may be defined under several headings:

- 1 Care of the sick and injured on active duty
- 2 Preventive medicine—to protect and safeguard the lives of active duty personnel and maintain them as best possible in a state of health and readiness
  - a Through preventive medicine and public health measures
  - b Research
  - c Industrial medicine
  - d Collecting information about diseases and public health problems of other countries
- 3 Maintenance of active programs for problems concerned with field medicine, aviation medicine and problems peculiar to naval medicine
- 4 Planning the best application of total resources within our manpower and economic potential and for the evacuation hospitalization care and rehabilitation of the sick and wounded in time of war. This entails
  - a Understanding of strategic and tactical concepts
  - b Knowledge of materiel workloads, risks and administration
  - c Active leadership and command in the field

In order to fulfill this mission it is essential that qualified members of the Medical Dental and Medical Service Corps attend the National War College, those of the services or the Industrial College of the Armed Forces or have had staff or command experience before assignment to higher position of such responsibility. This is necessary because the medical departments of the services are all integral parts of their respective services and in time of war must form one team with one aim. Therefore in time of peace this primary mission must never be obscured or dimmed by the purely professional aims and natural extension of patient care.

## Foreword

The United States Armed Forces Medical Journal is the medium for disseminating information of administrative and professional interest to all medical personnel of the Department of Defense. The Assistant Secretary of Defense (Health and Medical) and the Surgeon General of the several services invite all medical officers and officers of the Medical Service Corps, Nurse Corps officers and officers of the Veterinary Corps of the Armed Forces and the medical consultants of the Army, Navy and Air Force to submit manuscripts for publication in this Journal.

## MAN IN A SPACE VEHICLE

DAN C. OGLE *Major General USAF (MC)*

SCIENTIFIC REALITY today stimulates our imagination as did the fiction of Jules Verne in the last century. This author of sensational pseudoscientific romances of adventure wrote of fantastic technological developments and inventions, many of which have subsequently become realities. Our wonder was indeed stimulated by "Five Weeks in a Balloon," "Twenty Thousand Leagues Under the Sea," "A Trip to the Moon," "Around the World in Eighty Days," and "Hector Servados," one of his lesser known books which described life on a comet. Science is moving so rapidly that it is difficult to distinguish between reality and science fiction. I have heard reliable scientists say that we can do anything we really want to do.

Recently at a research conference in my office, Colonel John Paul Stapp reminded us that people in high places were continuing to write obituaries for space flight, yet the idea refuses to stay dead. For example, the Washington *Evening Star* of April 24, 1957<sup>1</sup> carried the announcement that fabrication had started on the X 15, a rocket powered research plane expected to fly higher and faster than any other manned aircraft, and that Pentagon officials had let it be known that the new craft may reach a speed of 4,000 miles an hour and fly as high as 200,000 feet. In my opinion, that is space flight. Since then there have been hints of an X 30, the nature of which I have no idea. Some conceive spaces outside our atmosphere, and others as beyond the earth's gravitational pull. Being interested in the human factors involved, I

Presented on 16 May 1957 in Birmingham Ala. at a symposium on "The Age of Space" sponsored by the Southern Research Institute. General Ogle is Surgeon General of the Air Force.

Reprinted from the U. S. Air Force Medical Service Digest 8-28 Sept. 1957

15/1

think of space flight as that which requires the traveler to take his environmental needs with him in a sealed cabin or capsule I could actually stretch my definition to include lower levels

Doctor Edward Teller<sup>1</sup> in an article entitled "Science in the United States" appearing in the *Air Force* magazine for April 1957 expressed himself as follows "I am talking about space travel about going to the moon Why should we? I haven't found a good practical reason I haven't found a good military reason I don't know how good and practical Columbus reasons were In the end something practical came of them" Doctor Teller goes on to discuss our interest in the unknown and unexplored which is the mainspring and justification of all adventures and expresses his personal concern that unless we expand our own scientific interests and capabilities the first close up pictures of the moon will be brought back by other than Americans

In recent publicity releases an aircraft corporation makes no apology for such statements as "Space travel, a dream five years ago is now so near reality that lunar landings are predicted by the end of this century With the possibility of interplanetary flight accepted by engineers man now looks to get him there is speculating on new power sources needed to get him there A predicted break through is the plasma engine which will harness ions or light itself to drive aircraft nearly 166 000 miles per second "I must admit here that I have never heard of such a predicted break through or of a "plasma engine" but the term did forcefully bring to my mind that the "plasma engine" with which have some familiarity—man himself—continues to be much the same old model having enjoyed no engineering improvements since generations before the dawn of history If space travel is to proceed much beyond that which is accomplished by air vehicles already in operation then much must be done to select train and sustain the human "plasma engine" in four dimensional environments that are becoming increasingly harassing and complex

We have not yet scratched the surface of human reaction to the fourth dimension of time as a factor in extraterrestrial environments Adapting people to this air age is still in its infancy Even yet we encounter people who doubt that the simple aircraft is here to stay We in the Air Force receive frequent complaints from people who resent aircraft noise and the occasional sonic boom is being accused of every type of destruction from impotency of minks to fractured dental plates

Publicly accepted or not, a rocket powered manned aircraft is reported to have flown approximately 2 000 miles per hour reaching an altitude nearly 24 miles I repeat that by my own definition that was space flight Within the next five years jet-powered air-

craft will be operating routinely as high as 16 miles at speeds around Mach 3. If not at this point, then shortly beyond lies the province of space, at these borders man needs much the same physical or environmental support as he requires in true space. Vehicles powered by rocket engines need no air either for lift or to burn their fuels, yet man's sensible atmosphere must accompany him wherever he goes, whether at altitudes of 16 miles or on a two year round trip to Venus—our closest neighboring planet.

### ACCLIMATIZATION TO SPACE

With this introduction I have attempted to establish the point that from the interests of aviation medicine and human engineering, space flight is now upon us, for earth bound man requires special medical and physiologic support almost from the time he leaves the ground. Properly selected and trained, he can fly well in an open cockpit up to an altitude of 10,000 feet. Breathing 100 per cent oxygen, he can go to between 30 and 40 thousand feet, but at these levels he needs added protection from decreased barometric pressure and from falling temperatures. Beyond this, oxygen must be supplied under pressure by mask, or by cabin or suit pressurization. No cabin pressurization system is foreseen that would carry the occupant of an air vehicle beyond 70,000 feet, as at this point the bulk of the equipment required to compress the thin air and the heat generated thereby are of such magnitude that a sealed cabin or capsule is mandatory.

Several years ago Major General Harry G. Armstrong,<sup>4</sup> in starting a space medicine department at the U. S. Air Force School of Aviation Medicine, called attention to successful animal carrying rocket flights and remarked that space medicine studies were indicated because, as he expressed it, "If monkeys can do it, we can learn to do it."

Many now scientific processes of recent years have forged interlocking bonds between medical science and engineering. Space medicine is linked with several scientific disciplines dealing with extraterrestrial matters. Recently some educators have gone so far as to recommend engineering as a prerequisite to the study of medicine, and earlier this month Doctor Harvey E. Savely<sup>5</sup> of the U. S. Air Force Office of Scientific Research, in a special report to the Aero Medical Association in Denver, called attention to various technologies and disciplines required for research in aviation physiology. In summary, his paper stated that advances in aircraft design are making less critical the traditional physiologic problems in environmental protection. They will always be a challenge, of course, however, he emphasized new environmental factors presented by radiation and unusual patterns of acceleration. New demands are being made on man's endurance and performance under a wide variety of complex situations. We are becoming

increasingly dependent on the applied aspects of medical or physiological dynamics psychology and physiology often referred to as human engineering. These applications indicate that research in aviation physiology will be characterized by increasing emphasis on the central nervous system and on the biochemical and biophysical aspects that have a regulatory influence on human health and effectiveness. The fundamental biological mechanisms underlying human behavior and performance demand great consideration in any circumstance of space flight.

It is vague in any scientific or research atmosphere to announce that we stand on the threshold of a great "break through." Any speaker who omits his break through routine is not up on current custom.

In any event the human body and mind are now revealing secrets hitherto believed as ephemeral as thought itself. The psychiatrists are at one with the biochemists and previously unknown enzymes and toxins are becoming the substance of psychoses or sanity. Various steroids, hormones and other biochemical substances may be valuable indicators of latent stability, resistance, anxiety, heroism or fear. Human chemistry may determine our susceptibility to collapse or disease and the electrophysical properties of the skin may tell the scientists our capacity for continuing awareness. The electrowaves of brain activity may act as a radar to warn of approaching impacts on the psyche.

These are human areas that must be more fully researched before we can select and fit candidates to withstand the traumatic influences of prolonged space living.

### HAZARDS OF UPPER ATMOSPHERE

To better understand the environmental hazards of space flight it is appropriate to discuss the characteristics of the upper atmosphere and space, the nature of feasible space vehicles, the forces and fuels required for such travel and the element of time as it relates to human tolerance and survival. The biophysical considerations imposed by the four areas just mentioned are very challenging. It is necessary that whatever is needed by man to adequately sustain him for the entire duration of any contemplated flight including air, water, food and recreation must be complete within the sealed capsule of the vehicle. In addition to a constant supply of these necessities, all waste materials must be eliminated or converted for re-use. If this capsule can be made efficient then the absence of ambient air *per se* does not pose a problem from the respiratory standpoint.

The engine of the machine itself may produce heat or radiation and certainly will result in accelerative and decelerative forces traumatic in nature at the start and at the termination of rocket

flights into space. But perhaps we will find that the most traumatic factor of all is that of time and confinement within a sealed cabin, traveling in a lonesome void. Even today in prolonged flight at present operational altitudes, we are encountering by-products of isolated monotony which Clark and Graybiel<sup>6</sup> of the U. S. Naval School of Aviation Medicine, Pensacola, Fla., describe as the "break off phenomenon" or a feeling of separation from the earth.

In addition to the break off phenomenon, we occasionally hear of vague yet disturbing and possibly fatal episodes of fascination or hypnotic reactions resulting from target or instrument concentration. Similar popular explanations are given as reasons for the occasional disappearance of skin divers, men in another environment foreign to normal human experience.

Woodburn Heron<sup>7</sup> in an article, "The Pathology of Boredom," said that "the problem of human behavior in monotonous situations is becoming acute." He was speaking of increasing automation—or dial watching. Heron reported a series of experiments and concluded that "normal functioning of the brain depends on a continuing aroused reaction (incident to) constant sensory bombardment." However, sensory stimuli rapidly lose their power to arouse if they are restricted to the monotonously repeated stimulation of an unchanging environment or circumstance. A quote from a concluding paragraph is as follows: "Prolonged exposure to a monotonous environment, then, has definitely deleterious effects. The individual's thinking is impaired, he shows childish emotional responses, his visual perception becomes disturbed, he suffers from hallucinations, his brain wave pattern changes."

The earth is surrounded by a sea of compressible air, 99 per cent of which lies within 20 miles above the earth's surface. We can readily see then that for practical purposes as far as oxygen is concerned, space is relatively near the earth. As we ascend to altitude and barometric pressure is decreased, the partial pressure of oxygen (and hence that available to us) is correspondingly decreased. At 18,000 feet the barometric pressure and partial pressure of oxygen are one half that found at sea level, at 33,000 feet, one fourth, at 38,000 feet, one fifth, at 50,000 feet, one ninth, and at 100,000 feet, one ninety fifth. These data emphasize the requirement for a sealed self-contained and self-sufficient cabin for human flight, now possible in aircraft type of "spaceships" already in being.

The layer of atmosphere adjacent to the earth is called the troposphere. Its thickness varies with latitude and seasons but averages about 35,000 feet. Within the troposphere lies more than 75 per cent of the atmospheric bulk and almost all of the storms and weather. Electromagnetic storms, however, are generated by

sun activity resulting in unusual ionie bombardment of our atmosphere. Electromagnetic radiation with energy sufficient to light up the northern lights to interfere with radio transmission and reception and to increase the earth's background of cosmic radiation is frequently reported. Such "storms" may present problems in space. At 60 000 feet protection from cosmic rays and ultraviolet radiation by the atmosphere begins to diminish. There has been much speculation concerning the hazard from cosmic rays and early fears seem to have been exaggerated. However, the final word on this has not yet been spoken.

The effects of cosmic radiation are now being studied at Holloman Air Force Base, New Mexico, where mice are being sent to extreme altitudes and observed for biological effects. Except for the possible effects of violent electromagnetic storms, data on which are incomplete, we are not exposed to significant primary cosmic radiation below 60 000 feet because of the protection afforded by the atmosphere. Secondary lower voltage rays do reach us at all levels but are believed to be relatively harmless. Some believe that protection against cosmic radiation similar to that afforded by the atmosphere can be taken over by a cabin's hull in space flight. On this point I cannot argue. Once the exact medical hazard is determined, protection should be a function of the engineer. Doctor Herman J. Schaefer of the U S Naval School of Aviation Medicine, an authority on cosmic radiation, warns that commercial airlines should not risk flight above 90 000 feet as it has not been proved that mutations or malformations following such flights were not caused by cosmic radiation.

During the winter 1953-1954 an aluminum covered film pack was struck by some strange particle from outer space during a research balloon test at 100 000 feet—the space particle went through the film pack like a bullet through a deck of cards. In doing so it produced a scientifically thrilling sequence of what appeared to be the conversion of earthly matter into energy and then a reconversion of this energy into another form of earthly matter. Such reports give us pause in contemplating space flight.—I'm sure a mutation fearing "ag" would spell pause with a "W."

At an altitude of 75 miles the atmosphere no longer has a protective function against meteorites. Although in space flight the probability of collision with meteorites is remote, some thought must be given to protection against them. Meteorite bumpers or meteor screens consisting of an outer layer of steel around the hull of spaceships have been suggested. Perhaps of more concern is the build up or accumulation of energy by a fast traveling spaceship. Doctor Heinz Haber, an astrophysicist, stated that at one twentieth the speed of light in space the

energy equivalent striking the ship would be as if  
suns, causing immediate vaporization. It must be pre-  
that somewhere far below such speeds there is an ac-  
cumulation barrier. I am not one to say that barriers can  
surpassed.

Also, at this altitude the scattering of visible light by the  
and molecules ceases. This brings about the so-called "blue"  
or twilight of space with the stars visible at all times, yet  
objects in sunlight dazzlingly bright against the blackness  
shade. At 75 miles the transfer of sound by the atmosphere  
ceases, thereby producing the quietness of space. These  
serve to emphasize the psychological break-off phenomenon previously  
mentioned.

### IMMINENCE OF ROCKET FLIGHT

Planetary space flight may not be a reality until some time  
in the distant future. However, rocket flight involving space  
travel from one point of the earth to the other is just around the  
corner. The Secretary of the Army<sup>10</sup> recently predicted the use  
of rockets as troop transports whereby soldiers could be quickly  
and silently dropped into enemy territory. Many of the problems  
involved in interplanetary travel will be involved in rocket travel  
from one point on the earth to another. The rocket will be shot  
from the earth by a short burst of propulsion with high G force  
acceleration and will coast in an elliptical course after power  
has been shut off. It will then glide to a point of descent.  
Such flights at altitudes of 100 miles or more and speed up to  
15 times that of sound are envisioned. In such flights, the  
problems involved in prolonged space flight will be encountered.

In the stratosphere, flight at great speeds produces  
amounts of heat because of the transfer of heat from air to  
to the skin of the aircraft. This heat effect has been called the  
"thermal barrier." Control of this heat is an engineering problem.  
However, at an altitude of 120 miles above the earth's surface  
the air is too thin to cause frictional heat effects at any speed.  
Therefore, above 120 miles the temperature of the cabin's hull  
is governed by the sun's radiation.

Accelerations or G forces occur in all flights during such  
maneuvers as pull out from dives or in turns. When a person is  
accelerating in the direction from his feet to his head, the forces  
of inertia act in the opposite direction, this is called positive  
G. When a person is accelerating forward and the forces of  
inertia are backward, it is negative G. Positive G forces tend  
to cause blackout, negative G forces, redout. In present day,  
high performance flying by the use of G suits and restraining  
devices, man has been able to withstand forces within the struc-  
tural limits of his aircraft. It may be a different story in the fu-  
ture.

sun activity resulting in unusual ionic bombardment of our atmosphere. Electromagnetic radiation with energy sufficient to light up the northern lights to interfere with radio transmission and reception, and to increase the earth's background of cosmic radiation is frequently reported. Such "storms" may present problems in space. At 60 000 feet protection from cosmic rays and ultraviolet radiation by the atmosphere begins to diminish. There has been much speculation concerning the hazard from cosmic rays and early fears seem to have been exaggerated. However, the final word on this has not yet been spoken.

The effects of cosmic radiation are now being studied at Holloman Air Force Base, New Mexico, where mice are being sent to extreme altitudes and observed for biological effects. Except for the possible effects of violent electromagnetic storms, data on which are incomplete, we are not exposed to significant primary cosmic radiation below 60 000 feet because of the protection afforded by the atmosphere. Secondary, lower voltage rays do reach us at all levels but are believed to be relatively harmless. Some believe that protection against cosmic radiation by a cabin's hull in space flight on this point I cannot argue similar to that afforded by the atmosphere can be taken over. Once the exact medical hazard is determined, protection will be a function of the engineer. Doctor Hermann J. Schaefer of the U S Naval School of Aviation Medicine, an authority on cosmic radiation, warns that commercial airlines should not risk flight above 90 000 feet as it has not been proved that mutations or malformations following such flights were not caused by cosmic radiation.

During the winter 1953-1954 an aluminum covered film pack was struck by some strange particle from outer space during a research balloon test at 100 000 feet—the space particle went through the film pack like a bullet through a deck of cards. In doing so it produced a scientifically thrilling sequence of what appeared to be the conversion of earthy matter into energy and then a reconversion of this energy into another form of earthy matter. Such reports give us pause in contemplating space flight—I'm sure a mutation fearing wag would spell pause with a "H."

At an altitude of 75 miles the atmosphere no longer has a protective function against meteorites. Although in space flight the probability of collision with meteorites is remote, some thought must be given to protection against them. Meteorite bumpers or meteor screens consisting of an outer layer of steel around the hull of spacecrafts have been suggested. Perhaps of more concern is the build up or accumulation of energy by a fast traveling spacecraft. Doctor Heinz Haber, an astrophysicist, stated that at one twentieth the speed of light in space the

ies concerning the use of plants for photosynthesis, oxygen production, and carbon dioxide removal in a closed system. So far in these studies carried on at the University of Texas, it has been found that about 23 kilograms of a certain green alga the *Chlorella pyrenoidosa*, are sufficient to balance the gas metabolism of one man. Such a photosynthetic gas exchanger may one day be useful. For instance, in manned satellites, possibly artificial photosynthesis may be achieved.

Experiments must be continued concerning the maintenance of a livable environment in a sealed cabin. Perhaps the exploration of other methods of supplying oxygen and removing carbon dioxide, and the reconversion of waste solids and fluids to a usable state, is the answer.

### NEW SELECTION METHODS LIKELY

You will recall that I have previously stated that there has been little change in the model or general equipment of human beings for thousands of years. I can say, however, that modern medicine is learning much more about ourselves and that progress made in the past few years is comparable to the break-throughs in other scientific areas. We are learning more of the mechanisms of the central nervous system, both in the electrophysical aspects and in the biochemical areas, and it may be that with this increased knowledge of the physics and chemistry of our central nervous system, of our endocrine system, and of our very emotional content, we will develop much better techniques and processes for the selection, adaptation, and maintenance of people who will some day be called upon to man spaceships. Such a person must be all that the best aviator is today as well as being constitutionally and emotionally suited for the physical and emotional traumatic influences of sealed cabins speeding, heaven knows where, through the awful silence of a timeless and a darkened sky.

I could remain entirely within the realm of reality by predicting that we may in the near future be able to select and adapt human beings for specialized environmental circumstances by blood studies and adjustments of various steroids, hormones, and enzymes, by urine studies to determine adrenal gland activity, by galvanic sensitivity tests of the skin to determine the threshold of central nervous system awareness, by determination and adjustment of metabolic processes, and by brain studies through selected area electroencephalography.

There is so much that we have just begun to learn or even suspect—so much we must know about ourselves as human beings, and human souls—before we can leave our mother earth a length of time and have hope of return. I think of travel beyond our own little world, I

rockets However it is calculated that we could tolerate the G forces of attaining a speed of 25 000 miles per hour in 8 minutes It takes such speed to break away from the earth's gravity into true space

In horizontal flight under the pull of the earth's gravity the airplane follows a curved line parallel to the curvature of the earth In higher supersonic speed ranges, centrifugal forces begin to counteract the earth's gravitational forces bringing on the phenomenon of decreased weight or subgravity At 18 000 miles per hour or 5 miles per second, a state of zero gravity is reached In other words the pull away from the earth exactly equals the pull of gravity toward the earth At a speed of 7 miles per second an object will break away from the gravitational control of the earth and an "escape velocity" will exist At the present time the state of zero gravity can be obtained in jet planes flying a parabolic arc for only one-half minute and in rockets for three or four minutes

Experiments concerning the psychological effects of weightlessness are being studied at the Air Force School of Aviation Medicine and have been studied at the Aero Medical Laboratory and the Aero Medical Field Laboratory Studies indicate that by adaption the effects of zero gravity may be overcome at least, by some people Various subjective symptoms have been reported during the weightless state Some have felt exhilarated others have become peculiarly uncomfortable some have become violently nauseated The subjective sensation of falling is produced, like going over the top of a roller coaster This is due to the disturbances of ordinary impulses which depend on the pull of gravity It is quite likely that man will be able to adjust to a prolonged state of weightlessness both psychologically and physiologically regarding muscle and position control However it is too early to say whether or not serious medical problems might not result The space vehicle designers say they can create required gravity by spinning the ship Time can only tell whether or not this will help or become our ever so great grandchildren's substitute for "sit down you are rocking the boat"

Sustained flight above 70 000 feet is only possible when man carries his own atmosphere in a hermetically sealed cabin This raises the interesting question of providing a closed ecological system in which man can live In a sealed cabin he needs oxygen to breathe and wastes as well as excess carbon dioxide and other body gases and wastes as excess water vapor The "climatization" of such a sealed cabin is one of the problems of today The School of Aviation Medicine has a sealed cabin simulator which now serves as a research tool and will later serve for indoctrination The possibility of future flights of a week or a month's duration has prompted the sponsorship of stud

ies concerning the use of plants for photosynthesis, oxygen production, and carbon dioxide removal in a closed system. So far, in these studies carried on at the University of Texas, it has been found that about 2.3 kilograms of a certain green alga, the *Chlorella pyrenoidosa*, are sufficient to balance the gas metabolism of one man. Such a photosynthetic gas exchanger may one day be useful. For instance, in manned satellites, possibly artificial photosynthesis may be achieved.

Experiments must be continued concerning the maintenance of a livable environment in a sealed cabin. Perhaps the exploration of other methods of supplying oxygen and removing carbon dioxide, and the reconversion of waste solids and fluids to a usable state, is the answer.

#### NEW SELECTION METHODS LIKELY

You will recall that I have previously stated that there has been little change in the model or general equipment of human beings for thousands of years. I can say, however, that modern medicine is learning much more about ourselves and that progress made in the past few years is comparable to the breakthroughs in other scientific areas. We are learning more of the mechanisms of the central nervous system, both in the electrophysical aspects and in the biochemical areas, and it may be that with this increased knowledge of the physics and chemistry of our central nervous system, of our endocrine system, and of our very emotional content, we will develop much better techniques and processes for the selection, adaptation, and maintenance of people who will some day be called upon to man spaceships. ## USE OF UROPEPSINOGEN DETERMINATION

"Determination of the concentration of pepsinogen in the urine can be technically practical and clinically useful. It may offer a better index of gastric peptic activity than does incubation and it has been useful in the differential diagnosis of peptic ulcer versus gastric carcinoma. Uropepsinogen values can aid in locating the site of hematemesis and can assist in the diagnosis of pernicious anemia. The response of uropepsinogen to hormone stimulation may provide many diagnostic as well as therapeutic indexes to endocrinological conditions.

# AEROTITIS MEDIA AND AEROSINUSITIS IN SUBMARINE TRAINEES

## A Prophylactic Study

JOHN H. SCHULTE *Lieutenant Commander MC USN*

**A**EROTITIS media and aerosinusitis are clinical entities that result from failure to equalize the pressure in the middle ear cavities and sinuses to that of an increasing or decreasing ambient atmospheric pressure. Armstrong<sup>1</sup> stated that aerotitis occurs when there is inadequate ventilation of the middle ear cavity during ascent or descent.

Barotrauma of the middle ear occurs less commonly from exposure to a decreasing atmospheric pressure. This is due to the movement of the eilia and the flutter valve action of the ostium of the Eustachian tube, which favor the flow of air from the tympanic cavity to the nasopharynx and oppose movement in the opposite direction. Swallowing, yawning, and similar physiologic actions open the ostium of the Eustachian tube, permitting the passage of small volumes of air. In a decreasing atmospheric pressure (ascent), there is little to hinder air flow from the middle ear to the nasopharynx.

When the atmospheric pressure is increasing, the pressure in the nasopharynx tends to hold the Eustachian tube closed. This makes it necessary to use forced swallowing, yawning, or the Valsalva maneuver to produce equilibrium in the middle ear cavity.

Any acute or chronic disease that produces edema or congestion of the mucosa or lymphoid tissue in the vicinity of the ostium of the Eustachian tube, makes equalization more difficult or even impossible. The effect of barometric pressure changes on the middle ear and sinuses may range from a minor hyperemia to serious pathologic changes with effusion, hemorrhage, suppuration, and rupture of the ear drum.

Teed<sup>2</sup> developed a system of grading the degree of damage to the ear as determined by otoscopic examination. In grade I aro-

---

titis media there is retraction of the tympanic membrane with peripheral blood vessel congestion. Grado II shows retraction of the drum with generalized redness in all quadrants. In grade III there is transudation of serum into the middle ear cavity, giving the drum a yellowish appearance. Grado IV shows hemorrhage into the middle ear cavity with or without rupture of the tympanic membrane. The middle ear drum may be filled completely with blood making the ear drum appear black.

Grado I aerotitis media causes pain and transient muffling of sound without loss of auditory acuity. The symptoms last 12 to 24 hours. Nose drops containing a vasoconstrictor will help to relieve the pain.

Patients with grado II aerotitis media complain of severe pain and some loss of hearing. Catheterization of the Eustachian tube may correct the drum retraction but does not reduce the pain or redness. Complete recovery with return of normal auditory acuity usually occurs in 24 to 48 hours.

A grado III aerotitis media causes pain, a feeling of fullness in the ears, loss of hearing and tinnitus. Inflation of the Eustachian tube and daily shrinkage of the tubal mucosa is the recommended treatment. Recovery usually occurs in three to five days. If the fluid is not absorbed within a week, some authors recommend myringotomy and suction.

Patients with a grado IV aerotitis media may have no pain whatsoever. A feeling of fullness in the ears, tinnitus, and a definite loss of hearing are the symptoms commonly noted. Auditory acuity is recovered in five to ten days, however, permanent partial deafness may occasionally result. When rupture of the tympanic membrane occurs it usually will heal completely in two to five days if infection does not supervene.

Shilling\* found that 27.5 per cent and 30 per cent of two groups of 558 and 708 otherwise healthy young men had difficulty leading to aerotitis media when subjected to increased atmospheric pressure. These men had been screened carefully for submarine service to eliminate those with a history of severe or chronic upper respiratory infections, ear disease, asthma, hay fever, and other related allergies. Presumably an even greater percentage of the general population would be so affected by atmospheric pressure changes, thus limiting them to some degree or precluding them completely from occupations involving commercial air travel, mining, commercial diving, and tunnel (caisson) work as well as hobbies such as amateur flying, skin diving, and spear fishing.

The effect on the military service is to limit the number of otherwise healthy men who can qualify for aviation submarine

service, deep-sea diving and salvago, and underwater demolition teams. Additionally, aerotitis media or arosinusitis may temporarily incapacitate men who are qualified in these military specialties. For this reason, a study was undertaken to evaluate the prophylactic effect of several different topical drugs on the incidence and severity of aerotitis media and arosinusitis.

### METHOD AND MATERIALS

This study was accomplished using the double blind technic. The drugs and saline solution were supplied in identical two ounce plastic squeeze bottles labeled consecutively from 0001 to 5000. Neo-synephrine Hydrochloride (brand of phenylephrine hydrochloride) 0.25 per cent, thonzonium bromide 0.5 per cent, phylephrine hydrochloride and thonzonium bromide in combination, and Biomidrin\*\* were the drugs used in this study. Normal saline was used as a control.

Phenylephrine hydrochloride is a widely used vasoconstrictor, known to have rapid and lasting effects and an almost complete absence of side reactions.<sup>6</sup> Thonzonium bromide is a synthetic wetting agent with a marked mucolytic action.<sup>7,8</sup> Biomidrin, in addition to containing a vasoconstrictor and a mucolytic agent, also contains an effective antihistaminic.<sup>9,10</sup>

A total of 4,676 consecutive candidates for submarine training were used as subjects in this study. Of these, 72 per cent were between the ages of 17 and 25, while 28 per cent were from 26 to 39 years of age. Each trainee received a thorough physical examination within four days prior to his pressure test. All were found to conform to the current physical standards for submarine service.

On the day of the pressure test, a history was taken including present illnesses and past history of acute and chronic upper respiratory infections, ear disease, asthma, hay fever, and related allergies. The ears, nose, and throat of each trainee were then examined. All candidates who had objective evidence of severe upper respiratory infection and those who were receiving any form of medical therapy for an upper respiratory infection were excused from the test and were not included in the study.

All the remaining candidates were instructed in the techniques of equalizing the pressure in their middle ears. Each trainee was then given a squeeze bottle and instructed in its proper use.

\*The author is indebted to the Nepera Chemical Co. Inc. Yorkers N. Y. for supplying all drugs and materials used in this study.

Brand name for preparation of Neomycin Sulfate 0.1 per cent. Gramicidin, 0.005 per cent. Thonzylamine Hydrochloride 1.0 per cent. Thonzonium Bromide 0.05 per cent. and Phenylephrine Hydrochloride 0.25 per cent.

Upon completion of the pressure tests, each trainee was asked if he had any difficulty or pain during the test, and his ears, nose, and throat were re-examined. The tympanic membranes were graded in accordance with Teed's classification. Mucous membranes of the nose were graded as normal or as slightly, moderately, or severely congested. The results were recorded, along with the pretest findings and code number of the drug used.

### RESULTS

There was no significant statistical difference between the findings on subjects in the 17 to 25 age group and those on subjects from 26 to 39 years of age.

As shown in table 1, there was physical evidence of injury to one or both ears of 1357 (27.9 per cent) of the subjects. Of the 234 (4.8 per cent) who also failed the pressure test, 230 failed because of earache, 3 because of sinus pain, and 1 for psychological reasons.

TABLE 1 Symptoms of aerotitis media and aerotympanitis as observed in entire group of subjects and in those having a history of allergy

Symptom or sign	Total group		Allergy group	
	Number	Per cent	Number	Per cent
Total	4876	27.9	186	54.3
Ear damage	1357	11.8	101	42.4
Ear pain	576	4.8	79	34.4
Failed test	234	3.3	64	4.8
Sinus pain	161	1.9	9	0.5
Toothache	96	0.9	1	1.6
Nose bleed	48		3	

A positive history for allergy was elicited from 186 of the 4876 candidates tested. Of these, 101 (54.3 per cent) incurred injuries to one or both ears. 79 had earaches, 9 had sinus pain, 3 had nose bleeds, and 1 developed a toothache. Sixty-four (34.4 per cent) failed because of earache. Two of these also had sinus pain.

None of the topical drugs tested exerted a significant prophylactic effect, and any differences observed were well within the limits of random variation. This was true not only concerning

observable ear damage (table 2), but also with reference to the occurrence of symptoms and the state of the nasal mucosa. In 186 subjects with positive histories of allergy, there was some indication that Biomidrin and thonzonium bromide may have been of benefit in reducing the incidence of symptoms and of damage to the sinuses and ears, but the size in this group was too small for definite statistical conclusions.

TABLE 2 Ear damage observed by otoscopic examination after pressure test following prophylactic use of various topical drugs

Test material	Grade of ear damage					Number of ears damaged	Total
	0	I	II	III	IV		
Total	7505	1189	551	406	99	2245	9752
Normal saline	1516	248	113	81	22	464	1980
Phenylephrine	1491	233	114	76	22	445	1936
Thonzonium	1513	236	110	84	23	453	1966
Phenylephrine & thonzonium	1493	210	110	86	17	453	1946
Biomidrin	1494	232	104	79	15	430	1924

### DISCUSSION

The high percentage of damage and failure among subjects with allergic histories supports the premise that they are a poor risk for occupations involving atmospheric pressure changes.

Aerosinusitis and toothache were found to be of relatively little importance in regard to failure to pass the pressure test. Only three failed because of sinus pain alone, and none failed because of toothache alone.

The remarkably low incidence of failure when compared to ear damage can be attributed to two reasons. First, submarine candidates are highly motivated, and their success in submarines is dependent upon their ability to pass the pressure test. Second, the degree of pain and discomfort may not be as severe as is indicated by otoscopic examination.

Comparison of those trainees having ear damage showed that the incidence and severity of pain were greater in those with grades I and II aerotitis media than in those with grades III and IV. It is reasonable to anticipate that pain will occur when the tympanic membrane is stretched and retracted, but understand

was not closely related to arterial hypoxemia. They considered that a normal arterial oxygen saturation could not be taken to mean that the patient was free of disability.

### CASE MATERIAL AND METHODS

One hundred consecutive patients with obstructive pulmonary emphysema were studied. The diagnosis was made by history, physical examinations, roentgenography, fluoroscopy and pulmonary function studies. A case did not have to present positive findings in all these areas to be classified as obstructive emphysema.

The patients were classified clinically into four groups according to the estimated degree of disability severity. The classification was based on statements made by the patient during the interview for clinical history. Except for slight modification the scheme established by the New York Heart Association\* for determining functional capacity was used in this study. The criteria were

#### Group I

- A The patients activity was not limited by dyspnea
- B They could walk an unlimited distance on the level at a normal brisk pace
- C They were able to climb three or more flights of stairs without stopping or experiencing undue discomfort
- D They were able to do prolonged work involving at least moderate exertion without stopping

#### Group II

- A In these patients there was a slight to moderate limitation of activity
- B They could walk several city blocks on the level without stopping or discomfort provided a normal pace was maintained
- C They usually were able to climb two flights of stairs without stopping. After one flight there usually was slight to moderate dyspnea but it was at the end of the second flight that dyspnea usually necessitated stopping or produced discomfort
- D Most of these patients were working full time at jobs with varied exertional demands. Some were doing farming or general labor

#### Group III

- A In these patients severe dyspnea usually imposed considerable limitation of activity

November 1957)

## PULMONARY EMPHYSEMA

1579

B They usually were unable to walk more than one or two city blocks on the level at a normal pace without pausing to rest

C They avoided stairs whenever possible, and one flight at a slow pace usually produced severe dyspnea

D They usually experienced marked weakness, easy fatigability, and the need for a great deal of rest and sleep

E Often, a mild degree of exertion was sufficient to produce paroxysms of cough

F Usually they were able to handle only sedentary work. The capacity to do part time work with frequent rest periods was occasionally described

### Group IV

A These patients often were dyspneic at rest

B They noted less daily variation in symptoms than did patients in Group III

C They usually were forced to rest before completing, at a slow walking pace along the level, a distance equivalent to one city block

D Stair climbing had been discontinued completely because of severe dyspnea and weakness

E They usually were unable to do any type of work, and on occasion needed assistance in eating, toilet, and dressing functions

An ear lobe oximeter as designed by Wood and Geraci<sup>7</sup> was used to determine arterial oxygen saturation. Values obtained by the oximeter were standardized by having the patient breathe 100 per cent oxygen, and the resultant values were considered to equal full (100 per cent) saturation. The patient was then tested on room air at rest and during exercise. Periodic checks of the oximeter readings were made against samples of arterial blood analyzed by a manometric technique.<sup>8</sup>

A standard exercise step test was used.<sup>10</sup> The patient performed the exercise for one minute or until dyspnea and fatigue made it necessary to stop. A maximum of three minutes was set for the exercise of the less disabled.

The clinical classification was determined before roentgenograms, physical examinations, fluoroscopies, or pulmonary function studies were evaluated. Detailed consent was given to interview techniques so as to obtain optimum relationships. The interview was conducted in setting, in preference to the open laboratory, and

to systematized questions and answers on "huffing and puffing". Each patient was provided an opportunity to talk about other problems and concerns insofar as possible the situation was "warmed" by personalized attention, in order to minimize the impact from machines and strange gadgets.

## RESULTS

As shown in table 1 79 per cent of the patients were classified in Groups II and III. It is apparent from the criteria used to determine functional capacity that a significant difference in severity of disability can occur between patients in these two groups and although the variation did extend from a slight to a severe degree of disability the occurrence of hypoxemia in the two groups was nearly identical. Of the 35 patients in Group II 45.7 per cent had hypoxemia at rest or exercise or both. Of the 44 in Group III 45.5 per cent had hypoxemia at rest or exercise or both while an additional 4.5 per cent had no hypoxemia at rest but were unable to exercise.

The differences in the severity of disability between Groups III and IV were not nearly as marked as between Groups II and III. In most instances it was difficult to separate patients into either Group III or IV because of similarities in the patterns of their disabilities. The patients' statements that they had symptoms at rest and experienced a lesser degree of daily variation in symptoms were an important factor in placing patients in Group IV. Despite the absence of striking differences in disability severity a notable difference in frequency of arterial hypoxemia was documented. Of the patients in Group IV 63.3 per cent had hypoxemia at rest or exercise or both while an additional 11.1 per cent had no hypoxemia at rest but were unable to exercise. This compares with 45.5 per cent and 4.5 per cent respectively for Group III. I was unable to correlate this difference between the two groups in frequency of hypoxemia with difference in degree of disability.

In the total series 51 per cent demonstrated hypoxemia at rest or exercise or both, while 4 per cent had no hypoxemia at rest but were unable to exercise. One patient in Group II and one in Group III showed hypoxemia at rest that returned to normal following the hyperventilation of exercise.

Table 1 demonstrates that hypoxemia could not be assessed as having a significant influence on exercise capabilities. Seventeen per cent of the total series had hypoxemia at rest and throughout the exercise stop test which they completed. Thirteen per cent had hypoxemia at rest but were unable either to start or to complete an exercise test. Therefore approximately the same number of patients who had arterial hypoxemia

severity of disability and presence of arterial hypoxemia

Incidence of arterial hypoxemia												
Classification of patients	None at rest unable to exercise		Present at rest, unable to exercise		None at rest or exercise		Present at rest and exercise		Present on exercise only		Present at rest only	
	Num ber	Per cent	Num ber	Per cent	Num ber	Per cent	Num ber	Per cent	Num ber	Per cent	Num ber	Per cent
Group I	3											
Group II	35				3	100	8	22.9	7	20.0	1	2.8
Group III	44				19	54.3	8	18.2	9	20.5	1	2.3

					1	5.6			19		2	
					45		17					
Total	100				45							

while at rest were able to complete the exercise test as were not able to complete it.

The importance of hypoxemia in cases of congestive failure in cor pulmonale in obstructive emphysema can be seen from table 2. Of 14 patients with congestive failure one was in Group III and 13 were in Group IV. Only three of the 14 patients were free of hypoxemia at rest, and one of the three was hypoxic after exercise. The other two were unable to exercise because of weakness and/or dyspnea. One of these two had systemic hypertension but the electrocardiogram demonstrated right axis deviation and the clinical signs were those of right heart failure. He had greatly increased lung volume with marked stigmata of air flow obstruction so was diagnosed as having cor pulmonale with congestive failure.

TABLE 2 Relation between severity of disability, arterial hypoxemia, and congestive failure in cor pulmonale in patients with pulmonary emphysema

Patients with emphysema		Patients with congestive failure	Incidence of hypoxemia		
			Hypoxic at rest	Hypoxic only on exercise	No hypoxemia but unable to exercise
Disability classification	Number	Number	Number	Number	Number
Group III	44	1	1	1	2
Group IV	18	13	10	1	2
Total	62	14	11	1	2

None of the 38 patients in Groups I and II had congestive failure.

## DISCUSSION

That arterial hypoxemia did not correlate closely with severity of disability may be related to the following difficulties encountered during the clinical classification.

1. A question occasionally arose as to the reliability of the patient's account of his capacity to tolerate exercise. This applied to cases where symptoms may have been minimized as well as to those where they may have been exaggerated.
2. There sometimes was a problem as to the proper and most effective interviewing technique for a given patient. Language barriers, vocabulary differences and hostility toward the situation were encountered and the ability to communicate varied greatly among individual patients.

3 A number of patients stated that there were periodic variations in the degree of their symptoms, with episodes that varied from daily to weekly or monthly. As a result, some patients were studied at a time when symptoms were maximum, while others were studied when symptoms were minimum.

That arterial hypoxemia did not appear to have an important influence on exercise capabilities could be related to the following facts:

1 As the chief symptoms, dyspnea and easy exhaustion impose a marked limitation on exercise tolerance. They are so readily and markedly aggravated by even minimal exertion that prolonged activity is usually impossible.

2 Arterial hypoxemia may be delayed in onset. This is characteristic of the so-called "prolonged desaturation time" in emphysema described by Woolf, Gunton, and Paul.<sup>11</sup> If these patients were able to do more prolonged exercising, arterial hypoxemia probably would occur in a greater number of cases and to a greater degree.

Labored breathing and easy exhaustion are the result of abnormalities in the mechanics of respiration. Increased air flow resistance manifested by inability to achieve a high rate of air flow during expiration, poor intrapulmonary mixing of gases, and large intrapleural pressure fluctuation during quiet breathing are the primary defects.<sup>12</sup> Increased force is required to move air into and out of the lungs. This force is supplied by the muscles of respiration increasing their work output. Alveolar hypoventilation is present because of poor intrapulmonary mixing of gases. The compensatory response to this is hyperventilation. A dilemma thereby exists for the emphysematous patient. He must meet the demands of alveolar hypoventilation by hyperventilating against resistant forces that increase the workload tremendously. Oxygen utilization is attained only by ventilating an abnormally large amount of air. This inefficient pattern of respiration is what is meant by the "increased work of breathing." Riley<sup>13</sup> has defined the work of breathing as the oxygen cost of breathing. He has demonstrated that patients with air-flow obstruction must produce a large minute volume to effect a relatively small amount of oxygen utilization. Normal subjects are able to effect a much more efficient relationship between minute volume and oxygen utilization.

The prolonged desaturation time may be a function of the large functional residual capacity and poor intrapulmonary mixing of gases. Because of these two abnormalities, the patient starts the test with a large volume of oxygen in his lungs and an inefficient washout mechanism. Oxygen is slowly absorbed from

poorly ventilated areas and remains in relatively high concentration in these areas because of poor washout

That congestive failure in cor pulmonale was limited almost entirely to patients with arterial hypoxemia raises the consideration of utilizing intermittent oxygen therapy. The importance of this therapy in patients with hypoxemia relates to current concepts of hypoxia and pulmonary hypertension. The effects of hypoxia on pulmonary circulation have been stressed by a number of investigators,<sup>14-16</sup> who have found a highly significant correlation between anoxia and increased pulmonary artery pressure. In their opinion anoxia is of definite importance in the genesis of pulmonary hypertension. When intermittent oxygen therapy is not utilized to combat chronic anoxia other approaches to the problem would include

- 1 Improving air flow dynamics and intrapulmonary mixing of gases by mechanical and pharmacologic means
- 2 Effecting further control of situations and activities that aggravate the degree of hypoxia
- 3 Investigating biological and mechanical means whereby oxygen storage capacity can be improved. Nature has provided man with the capacity for storing a 40 day supply of carbon compounds from which energy and building materials for cellular activity can be derived. However, should the flow of fresh oxygen be cut off from the arterial blood man has but a four minute supply of oxygen with which to burn this bountiful harvest of stored carbon compounds.

### CONCLUSIONS

Arterial hypoxemia did not correlate closely with the degree of disability or with tolerance to exercise in patients with pulmonary emphysema. The individual patient with either slight or severe disability may have a normal arterial oxygen saturation. These results indicate that the severity of disability in a case of emphysema cannot be judged by knowing only the status of arterial oxygen saturation.

The presence of congestive failure in cor pulmonale was almost entirely limited to patients with hypoxemia. The incidence was greatest in those patients with persistent (resting) hypoxemia.

### SUMMARY

A study was made to determine the correlation between the degree of disability and arterial hypoxemia in 100 consecutive patients with chronic obstructive pulmonary emphysema. The diagnosis in each case was based on combined clinical findings

and pulmonary function studies. The patients were classified in four groups according to an estimation of the severity of disability based on statements made during the interview for clinical history. Except for slight modification, the criteria established by the New York Heart Association for grading functional capacity, or disability severity, were utilized.

A continuous recording ear-lobe oximeter was used to determine arterial oxygen saturation. Periodic checks of the oximeter readings were made against samples of arterial blood analyzed by manometric technique.

Poor correlation was found between arterial hypoxemia and the clinical profile of disability severity, indicating that disability cannot be assessed solely on the basis of the degree of arterial oxygen saturation. The importance of arterial hypoxemia on hemodynamics in the pulmonary circulation is discussed, and certain approaches to the problem are suggested.

## REHABILITATION OF THE CARDIAC PATIENT

"The process of rehabilitation begins at the moment the patient is first stricken with his disease. The goal is the maximal attainment within the patient's capacities. In approximately 80 per cent of cardiac patients the total program can be managed by the private physician; in others a team approach and help from specialists is necessary. It is assumed that adequate attention has been given to medical therapy, rest, relief of pain, oxygen requirements, nutrition, and sedation. In addition, the patient's emotional problems must be dealt with. The period of passivity which is frequently required at first should be terminated as soon as possible. The periods of hospitalization and of convalescence at home are followed by a period of vocational readjustment, and each presents problems that can be solved on the basis of available facts. There has been no evidence that employment has aggravated the underlying disease in cardiac patients, and there have been no medicolegal compensation cases involved in the employment of such patients."

# JELLYFISH STINGS AND THEIR MEDICAL MANAGEMENT

BRUCE W. HALSTEAD *Lieutenant Commander MC USNR*

**S**TINGS from jellyfishes and related coelenterates are of frequent occurrence among swimmers, fishermen, and skin divers. Because of the nature of their activities, jellyfish stings are not uncommon among naval personnel. Fortunately, most coelenterate stings are mild in nature, and cause only minimal discomfort to the victim. In rarer instances they can produce serious injury, and on occasion sudden death. The purpose of this article is to discuss the medical significance of certain coelenterates that are considered to be especially dangerous to man, and the medical management of their stings.

## CLASSIFICATION

The phylum Coelenterata, in which are grouped hydroids, jellyfishes, sea anemones, and corals, consists of simple metazoans having primary radial, biradial, or radiobilateral symmetry. They are composed essentially of two epithelial layers and but one internal cavity, the gastrovascular cavity or coelenteron, which opens only by the mouth. A dominant character of the group is the presence of tentacles equipped with nematocysts, or "stinging cells." The phylum Coelenterata generally is divided into three classes.

### Hydrozoa (the hydroids)

To this class belong the hydroids that are commonly found growing in plumelike tufts on rocks, seaweeds and pilings. Small medusae are budded from these branching polyps. One of the most common stinging members of this group is *Physalia*, the Portuguese-man-of-war, which is a pelagic colonial medusa.

### Scyphozoa (the jellyfishes or true medusae)

This class includes the larger medusae having eight notches

This research was aided by a contract payment to the School of Tropical and Preventive Medicine, College of Medical Evangelists, Loma Linda, Calif., from the School of Aviation Medicine, U. S. Air Force, Randolph Air Force Base, Tex., and a grant from the U. S. Public Health Service.

in the margin of their bell. The deadly cubomedusae or box wasps, *Chiropsalmus* and *Carybdea*, are examples of this class.

*Anthozoa* (the sea anemones, corals and alcyonarians or soft corals)

The medusan stage is absent in this group, and many of the polyps are colonial. The corals are notable for their precipitation of calcareous skeletal structures and their role as reef builders. Important venomous examples are the anemones, *Sagartia*, *Actinia*, and *Anemonia*.

## COELENTERATES ESPECIALLY DANGEROUS TO MAN

### Hydrozoans

*Millepora alcicornis* Linnaeus—stinging coral, false coral, fire coral (fig. 1). Tropical Pacific, Indian Ocean, Red Sea, and Caribbean Sea.

Figure 1 *Millepora alcicornis* Linnaeus—stinging coral

*Physalia physalis* (Linnaeus)—Portuguese-man of war, blue bottle (fig. 2). Tropical Atlantic, occasionally as far north as the Bay of Fundy, the Hebrides, and Mediterranean Sea.

*Physalia utriculus* (La. Martiniere)—Portuguese man of war, blue bottle. Indo-Pacific, as far north as southern Japan, and Hawaiian Islands.

Figure 2 *Physalia physalis* (Linnaeus)—Portuguese man of war

### Scyphozoans

*Carybdea alata* Reynaud—sea wasp (fig 3) Tropical Pacific, Atlantic Ocean, and Indian Ocean

*Chironex fleckeri*\* Southcott—Queensland and Northern Territory, Australia

*Chiropsalmus quadrigatus*\* Haeckel—sea wasp (fig 4) Northern Australia, Philippines, and Indian Ocean

*Chiropsalmus quadrumanus* (Müller)—sea wasp from Brazil to North Carolina, Indian Ocean, Australia

---

*C. fleckeri* and *C. quadrigatus* may be the same species

Figure 3 *Carybdea alata* Reynaud—sea wasp

*Cyanea capillata* (Linnæus) (fig 6)—sea blubber, hairy stinger, sea nettle North Atlantic and Pacific, southern coast of New England to the Arctic Ocean, France to northern Russia, Baltic Sea, Alaska to Puget Sound, Japan, and China Other stinging species of this genus are found in the tropical and temperate Pacific Ocean

*Dactylometra quinquecirrha* Desor—sea nettle (fig 7) Azores and New England to the tropics, West Africa, Indian Ocean, western Pacific from Malay Archipelago to Japan, and Philippines

#### Anthozoa

*Acropora palmata* (Lamarck)—elk horn coral Florida Keys, Bahamas, and West Indies

Figure 4 *Chiropsalmus quadrigatus* Haeckel—sea wasp

*Actinia equina* Linnaeus—sea anemone (fig 8) Eastern Atlantic from Arctic Ocean to Gulf of Guinea, Mediterranean Sea, Black Sea, and Sea of Azov

*Anemonia sulcata* (Pennant)—sea anemone (fig 9) Iceland to Atlantic coast of France, Mediterranean Sea, and coast of Africa

#### VENOM APPARATUS OF COELENTERATES

The venom apparatus of coelenterates consists of nematocysts, or stinging cells. The term stinging cell actually is a misnomer, however, inasmuch as the structure is not a cell, but rather an organoid that is thought to be composed of chiton (fig 10). Nematocysts usually are most abundant on tentacles, grouped on protuberances and circular or spiral ridges. They also are

Figure 5 *Chiropsalmus quadrumanus* (Müller)—sea anemone

found in the epidermis of the oral region, and on internal tentaclelike structures, i. e. the gastric filaments, the septal filaments, and the acontia. Nematocysts initially develop inside interstitial cells, termed cnidoblasts or nematocytes. The developmental site of the nematocyst is usually some distance from the region in which it is finally utilized. Transportation of the cnidoblasts containing developing nematocysts is by amoeboid movement through the body wall or by way of the gastrovascular cavity to their final destination in the ectodermal epithelium.

The essential features of the nematocyst apparatus are as follows. The capsule like nematocyst is contained within the outer cnidoblast, which is fixed in the epidermis by a slender stalk connecting with the mesogloea. Projecting at one point on the outer surface of the cnidoblast is the triggerlike cnidocil.

Figure 6 *Cyanea capillata* (Linnaeus)—sea blubber Figure 7  
*Dactylometra quinquecirrha* Desor—sea nettle

Near the base of the cnidocil, in the periphery of the cnidoblast, there usually is found a circlet of stiff rods, probably of a supporting nature, and frequently a basketwork of sinuous fibrils that extend down into the stalk of the cnidoblast. Contained within the fluid filled capsule is the hollow, coiled, thread tube containing the folded spines. The opening through which the thread tube is everted is closed prior to discharge by a lidlike device called the operculum. The fluid within the capsule is the venom. Stimulation of the cnidocil appears to produce a change in the capsular wall of the nematocyst causing the operculum to spring open and the thread tube to evert (fig 11). The exact nature of the mechanism is not understood.

Figure 9. *Anemonia sulcata* (Pennant)—sea anemone

Figure 10. Undischarged stinging cell or nematocyst of a coelenterate. Note the coiled threadlike tube which conveys the venom. (Semidiagrammatic, greatly enlarged)

### MEDICAL ASPECTS

There are no accurate statistics regarding the incidence of jellyfish stings among American military personnel, but Southcott<sup>1</sup> stated that while serving as regimental medical officer to a battalion attached to an Australian beach group at Palm Beach, north of Cairns, Queensland, during the period from December 1943 to January 1944, there were about 100 persons stung by jellyfish. One would assume from this that the over all incidence is probably quite high. Unfortunately, there is even less information available regarding other types of coelenterate stings.

#### Clinical Characteristics

The symptomatology of coelenterate stings varies according to the species, the site of the sting, and the person. In general, the symptoms produced by hydroids and hydroid corals are primarily local skin irritations. Sea anemones and true corals produce a similar reaction, but this may be accompanied by general

Figure 11 The discharged stinging cell or nematocyst of a coelenterate (Semidiagrammatic greatly enlarged)

symptoms. Ulcerations of the skin may be severe in the sponge-fishermen's disease produced by *Sagartia*. Symptoms resulting from siphonophores and scyphozoans vary greatly. *Physalia* stings may be very painful. The sting of most scyphozoans is too mild to be noticeable, whereas *Cyanea Dactylometra*, *Chiropsalmus*, and *Chironex* are capable of inflicting very painful local and generalized symptoms. *Chiropsalmus* and *Chironex* are probably the most venomous marine organisms known and may produce death within 3 to 8 minutes in man.<sup>1-4</sup>

Contact with the tentacles of coelenterates results in symptoms ranging from an immediate mild prickly or stinging sensation like that of a nettle sting to an intense burning, throbbing, or shooting pain which may render the victim unconscious

In some cases the pain is restricted to an area within the immediate vicinity of the contact. In others it may radiate to the groin, abdomen, or axilla, depending on the initial site of the lesion, or it may become somewhat generalized. The local pains may be followed by a feeling of numbness or, sometimes, hyperesthesia. The area coming in contact with the tentacles usually becomes erythematous. This is followed by pronounced urticaria, blistering, swelling, and petechial hemorrhages. In sponge-fishermen's disease there may be a rash that becomes cystic, followed by multiple abscesses, necrosis, and sloughing of the tissues. Jellyfish may cause redness and flushing of the face, increased perspiration, lacrimation, coughing, sneezing, and rhinitis. An asthmatic-like condition has been reported as a result of inhaling dust containing dried jellyfish tentacles.<sup>9</sup>

The above-mentioned signs and symptoms may be accompanied by headache, malaise, primary shock, collapse, faintness, pallor, weakness, cyanosis, nervousness, hysteria, chills, and fever. In severe cases there may be muscular cramps, abdominal rigidity, diminished tactile and temperature sensation, nausea, vomiting, backache, aphonia, frothing at the mouth, sensation of constriction of the throat, respiratory distress, paralysis, delirium, convulsions, opisthotonos, cardiac standstill, and death.

The recovery period varies from a few hours to several weeks. Gunn<sup>10</sup> reported a case in which there was complete disappearance of the subcutaneous fat in the vicinity of the lesion. Stings from coelenterates may result in developing a sensitivity to the toxin, and a subsequent sting may produce a fatal anaphylactic reaction. An important factor in jellyfish sting fatalities is primary shock and subsequent drowning before the victim can be rescued.

The following case report is representative of the more severe types of coelenterate stings.

#### CASE REPORT

A six year old Filipino boy was swimming in about 2 feet of water at Camantilis, Hundred Islands National Park, Pangasinan, Luzon. His sudden piercing screams brought several men running to his rescue. One of the men found a jellyfish by the side of the boy. Within moments the child was picked up and rushed to his home, which was within 10 yards of the seashore. He was found to be frothing at the mouth, and his respiration was spasmodic. His arms appeared to be partially paralyzed. There were large, irregularly shaped, dark brown welts on his chest, arms, and neck, wherever the tentacles of the jellyfish had come in contact with his body. In less than five minutes after his rescue the child died. After his death his face, neck, and arms became severely swollen.

The jellyfish measured about 6 inches in diameter with tentacles four feet in length. The organism was later identified by some of the local authorities as *Chiropsalmus quadrigatus* Haeckel.

### Treatment

A variety of measures have been suggested for the therapeutic management of coelenterate stings. Treatment must generally be directed toward accomplishing three primary objectives: relieving pain, alleviating neurotoxic effects, and controlling primary shock. Morphine sulfate has been found to be effective in relieving pain. Intravenous injections of calcium gluconate have been recommended for the control of muscular spasms. Histaminics by mouth and topical cream are useful in treating the urticarial lesions. Dilute ammonium hydroxide, sodium bicarbonate, olive oil, sugar, ethyl alcohol, and other types of soothing lotions have been used with varying degrees of success. Artificial respiration, cardiac and respiratory stimulants, and other forms of supportive measures may be required. The use of steroids also has been suggested. There are no known specific antidotes for coelenterate venoms.

### Preventive Measures

Particular care should be exercised by bathers swimming in areas in which dangerous coelenterates, especially the cubomedusae, *Chiropsalmus*, *Chironex*, *Carybdea*, and *Physalia*, are known to exist. It should be kept in mind that the tentacles of some species may trail a great distance from the body of the animal; consequently, they should be given a wide berth. Tight-fitting, long, woolen underwear or rubber skin diving suits are useful in affording protection from attacks from these creatures. Jellyfish washed up on the beach, even though appearing dead, may be quite capable of inflicting a serious sting. The tentacles of some jellyfish may cling to the skin. Care should be exercised in the removal of the tentacles, or additional stings will be received. Use a towel, rag, seaweed, stick, or handful of sand. Swimming soon after a storm in tropical waters in which large numbers of jellyfish were previously present may result in multiple severe stings from remnants of damaged tentacles floating in the water. Upon being stung the victim should make every effort to get out of the water as soon as possible because of the danger of drowning. Diluted ammonia and alcohol should be applied, and other therapeutic measures should be instituted as promptly as possible.

Since coral cuts are frequently associated with coral stings, a few remarks regarding these lesions are pertinent to the general subject. Anyone handling or wading around corals soon suffers from their sharp traumatogenic exoskeletons.

If coral cuts are left untreated, a mere scratch may within a few days become an ulcer with a septic sloughing base surrounded by a painful zone of erythema. In general, the symptoms appear to be far in excess of the visible lesions present. The severity of coral cuts is probably due to a combination of factors: laceration of tissues, introduction of foreign substance into the wound, i. e., minute bits of calcium carbonate from the animal's exoskeleton and possibly nematocyst venom, secondary bacterial infection, and adverse climatic and living conditions. Treatment consists of prompt cleansing of the wound, removal of foreign particles, débridement if necessary, and the application of antiseptic agents. In severe cases it may be necessary to give the patient bed rest with elevation of the limb, knolin poultices, magnesium sulfate in glycerin solution dressings, and antibiotics.<sup>11-13</sup> Levin and Behrman<sup>14</sup> found roentgen therapy to be useful in resolving a chronic coral ulcer with keloidal formation.

### TOXICOLOGY

The venom of coelenterates is believed to contain three toxic fractions:

#### Thalassin

According to Richot,<sup>11-12</sup> Pawlowsky,<sup>21</sup> and Maass,<sup>22</sup> intravenous injection of this fraction into dogs was found to produce sneezing, pruritus, urticaria, genital excitation, vasodilatation, edema of the face, nervousness, redness, coughing, rhinitis, rolling on the ground, conjunctivitis, nervous depression, cardiac arrest, and death. Thalassin is especially characterized by its pruritogenic properties. The lethal dose in dogs is said to be 0.02 gram per kg. Thalassin was first obtained from the tentacles of *Anemonia sulcata*, but is believed to be present in most other coelenterates.

#### Congestin

According to Richot,<sup>11-12</sup> 20-21, 24-27 Pawlowsky, and Maass,<sup>22</sup> intravenous administration of the poison into dogs resulted in vomiting, bloody diarrhea, evidence of abdominal pain, prostration, decrease in blood pressure, intense splanchnic vasodilatation, respiratory paralysis, and death. Congestin received its name because of the characteristic intense splanchnic congestion that it produces. The lethal dose in dogs is said to be 0.005 gram per kg of animal weight. This drug was likewise first obtained from the tentacles of *Anemonia sulcata*. Dujarric de la Riviere<sup>23</sup> isolated a substance from the tentacles of the jellyfish, *Rhizostoma cuvieri*, which he termed medusocongestin; however, it is believed to be identical with congestin.

## Hypnotoxin

This substance is characterized by producing a central nervous system depression affecting both motor and sensory elements. Symptoms most commonly encountered are inactivity, coma, muscular paralysis, and cutaneous anosthosis when injected intramuscularly into laboratory animals. Death was reported from respiratory paralysis, but the lethal dose is not known. Hypnotoxin was first obtained by Portier and Richet<sup>10, 11</sup> from the tentacles of *Physalia*.

## CHEMISTRY

Richet<sup>7-11, 12</sup> distinguished between thalassin and congestin on the basis of difference in solubility in alcohol. Ackermann, Holtz, and Reinwein<sup>13</sup> investigated the problem of the structure of coelenterate venom and believed it to be identical with tetramethylammonium hydroxide. Proof of identity was said to be in the coincidence of certain physical properties of a number of derivatives of the toxin as compared to the properties of the same derivatives prepared from this quaternary base. The question that remains is whether all of the physiologic properties ascribed to thalassin can be accounted for in terms of tetramethylammonium hydroxide. A subsequent study by Sondorhoff<sup>14</sup> did not provide an answer to this question. More recently Kelsch<sup>15</sup> has reported that the pain producing factor in coelenterate tentacle extracts is probably serotonin (5 hydroxytryptamine), whereas paralysis could be due to two or more related quaternary ammonium bases such as tetramethylammonium and urocanyl choline.

According to Portier and Richet<sup>10, 11</sup> hypnotoxin is believed to be a heat-sensitive, nondialyzable toxin with protein properties. Crutchfield<sup>16</sup> corroborated the heat sensitivity of the toxin and observed that it was digestible by trypsin. Little else is known about the chemistry of these interesting venoms.

## SUMMARY

Stings from jellyfishes and related coelenterates are of frequent occurrence among persons swimming in tropical waters. The venom apparatus of coelenterates consists of the nematocysts or "stinging cells" that are largely located on their tentacles. The symptomatology of coelenterate stings varies according to the species, the site of the sting, and the person. Deaths from some species of jellyfish may occur within 3 to 8 minutes. Morphine sulfate, calcium gluconate, histaminics by mouth, and various soothing lotions have been used in the treatment of these stings with varying degrees of success. Coelenterate venom is believed to be comprised of three basic fractions, which have been called thalassin, congestin, and hypnotoxin. The principal

effects produced are pruritus, vasocongestion, and circulatory system depression, respectively. Little is known of the chemistry of the venoms. It is believed, however, that pain-producing factor is probably serotonin (5-hydroxytryptamine) and that paralysis may be due to two or more related quaternary ammonium bases such as tetramethylammonium and triethylcholine. The dearth of reliable scientific data on this subject suggests the need for additional research on coelenterate venoms.

**ACKNOWLEDGMENTS** The author is indebted to Mr. Claro Martin, Chief Fisheries Research Division, Bureau of Fisheries, Republic of the Philippines, for the case report; to Dr. Donovan Courville and Mr. Don R. Coe, School of Medicine, College of Medical Evangelists, for the summarization on coelenterate venom; and to Mr. Robert Arcusinger, College of Medical Evangelists, for the preparation of the illustrations.

## IMPAIRMENT FROM ALCOHOL

The effects of alcohol vary with individual tolerance and length of usage. In an individual of average weight two ounces of whiskey are enough to produce a blood alcohol level of 0.05 percent—an amount sufficient to produce an average impairment of 25 percent. Alcohol is eliminated from the blood at the rate of about one third of an ounce per hour. Physiological impairments thus are likely to last for hours depending on the amount consumed.

## Reflections on Aircraft Accidents and Their Prevention

FRANK B. BERRY M. D.

*Daedalus and his son Icarus are two earliest recorded flyers. They were Athenians and went to the Island of Crete to build a labyrinth. Eventually they themselves were imprisoned there. In order to escape, Daedalus made a pair of wings for each which were held to the body by some form of wax. Daedalus warned his son Icarus not to get too near the sun as the wax would melt. They both escaped from the labyrinth but Icarus did not obey his father's warning and as a result of flying too high and getting too near the sun, he fell into the sea and drowned. Daedalus, on the other hand, arrived safely in Sicily. These are early examples of both faulty engineering, although Daedalus probably used the best materials that were available, and pilot failure in that Icarus did not obey the instructions of his father, the engineer who knew of the weakness in the flying equipment which he had designed.*

**A**T DUSK one evening some years ago I stood by the edge of a British air field in North Africa and watched the flight of bombers take off in exact precision, one after the other, for their evening bombing run. Except for enemy action there was never a thought but that they would all return safely to their base. There were no weather problems, the pilots and crews were well trained and maintenance was good. There was the will to co-operate and do the best job possible.

During the month of February 1956, we witnessed almost without comment, other than the factual recording of each, a sobering series of fatal airplane accidents for almost all of which there was no question of weather. To list a few, we had a B 52, two B 47s, a B 50, a Navy jet, a Marine transport, and chartered British Army transports in Egypt and Malta. In addition, we have had our own transport accidents in the past—the commercial, the larger military and chartered military planes—and here again frequently there was no question of bad weather. We are becoming

---

The second Louis H. Bauer Lecture Presented April 16, 1956 at the 27th annual meeting of the Aero Medical Association, Chicago. Reprinted from *The Journal of Aviation Medicine* 27: 197-207, June 1956.

Dr. Berry is Assistant Secretary of Defense (Health and Medical), Washington, D. C.

calloused to fatal accidents involving our youth both by the automobile and the airplane, and the public is comparatively unaroused by them, yet I am sure that the parents and wives have wondered. Must we accept this increasing toll or can something be done about it?

In an informal report and also in recent testimony before Congress I have deplored the fatalities incurred in routine training of pilots, crews and cadets both in the Air Force and Naval Aviation. As I ponder this question it seems to me there are several causes involved. At the moment we can do something about some of them, although for the time being the others may be beyond our ken as are the new problems that are bound to arise from our rapid technological advances. In order to protect and preserve these young men, it is of the utmost importance that we exert every effort to minimize their loss, even when in so doing the chips may fall in some places where they hurt. I speak not only of military aviation but also of civilian, and although the problems are somewhat different in both, they are also similar.

### THE BACKGROUND

As I have discussed in earlier addresses dealing with problems of personnel, we have been and still are in a period of short supply of manpower due to the decreased birth rate in the 1930 decade, and are only now beginning to approach the same monthly figure of boys turning eighteen years old as was the case in the mid 1940's. Within the next two or three years we shall exceed it and our pool of manpower will begin to mount rapidly. In a special report "Some Figures That Startle the Cabinet" in the February *U S News and World Report* there is a summation of this situation. Army tests show that one in nine youths examined were too illiterate for the Armed Forces (11 per cent), and of those accepted for training one in every three examined were found to be unsuitable for advanced training (33.3 per cent), which decreases available manpower still further.

Although the number of graduates from our medical schools is increasing at a slightly higher rate than is our population, this comparison is only valid *per se*. It does not take into account the rapidly expanding demands of our changing civilization. In 1900, for example, our population was 76 000 000 and in 1950 it was 157 700 000 slightly more than double. You may think that this can be readily explained because of the rapid advances in preventive and therapeutic medicine and surgery during this half century, and there is no question but that these are extremely important contributing agents. But there are complicating factors, for during this same period our Negro population almost doubled from 8 800 000 in 1900 to 15 000 000 in 1950 and in the same fifty years well over 20 000 000 of the total increase in population was

due to immigration. So what would have happened to our intrinsic growth rate had the composition of the population remained unchanged after 1900 is open to speculation.

From an educational viewpoint, to quote President Griswold of Yale<sup>11</sup>

At any one time in this country between the years 1900 and 1950 there are (and this would have held true for any month in any year you might have taken the measurement) between ten and thirteen million foreign born with between fifteen and twenty five million children giving a total of between twenty five and thirty-eight million foreign born citizens and their children.

To further confuse one, a similar increase in birth and decrease in death rates occurred during the 60 years of the reign of George III of England, from 1760 to 1820, when the population of Great Britain doubled. And this occurred in a small land area during a period of emigration rather than immigration. Those were the early years of the industrial revolution and, although there were some general improvements in living, the only significant purposeful medical development was the introduction of vaccination against smallpox by Dr. Edward Jenner at the very end of the eighteenth century. Except for this, forward steps in preventive medicine were almost nil. Fortunately, however, and this may have been a real contributing factor, the plague which was prevalent in England in the fourteenth to seventeenth centuries had not reappeared in epidemic form since 1665.

During the years since World War II there has been an extraordinary demand for trained skills, an increase in the old and development of new ones. Consider if you will what has happened: the great expansion in our automobile, aircraft, and air conditioning and electric appliance industries. To these we have added television, radar and electronics and our nuclear industries and research. Likewise, as you know, research has expanded enormously so that in 1952 it was estimated that 175,000 persons in this country were engaged in research, with an annual expenditure of about three and one half billion dollars. From the medical standpoint alone, our total costs today are in the neighborhood of two hundred million dollars annually. In 1940 the Federal Government contributed twenty five thousand dollars a year to the medical schools, whereas in 1954 its contribution was in the vicinity of fifty million dollars. We have to ask ourselves what price research, yet constantly new avenues are opened which must be followed, first, for their own intrinsic worth, and second, because they in turn lead to new sources of information. It may be wrong, therefore, to accept the conclusion that as long as our group of medical graduates is increasing at a slightly greater rate than that of the general population, all is well, our

apparent and real shortages may not be entirely a matter of distribution

In order to produce 2 800 qualified aviation cadets with two years or more of college education an original pool of 800,000 young men is required By the time those potential pilots reach the age of 40 the number of those remaining in the service is still further reduced

### THE PROBLEM

Today aviation is confronted with problems such as man has never had to cope with before Lacking the emotional drive which existed in the war years a decade ago, has there been a letdown on our part which accentuates those problems in their stark reality?

I have mentioned the series of fatal aircraft accidents that occurred in a recent month, in almost all of which there was no mention of a weather factor In a recent review of acceleration and human performance Brown and Lechner<sup>2</sup> cited as follows

Blockley has distinguished between two kinds of protection which must be afforded pilots One he labels emergency protection This is the kind of protection which is necessary for the preservation of life It would include such items as oxygen supply for use in high altitude a method of pressurization for use in extremely high altitudes and ejection devices The second kind of protection he calls basic protection This includes all techniques and devices for the maintenance and improvement of pilot efficiency Actually with the present rate of development in aircraft Blockley's basic protection is becoming more and more important for the preservation of life The demands which are imposed on pilots are such that unless they can maintain performance at the highest possible efficiency their chances of survival are appreciably diminished This is attested indirectly at least by the high percentage of aircraft accidents which are attributed to pilot error

According to Stieglitz Pilot error is the most common cause of accidents

And Roscoe reports Some pilot error exists in approximately 90 per cent of all aircraft accidents It would seem that the efficiency of pilot performance has not kept pace with the increasing demands as aircraft are improved

The knowledge of these demands is common to all of you, and as you accept "pilot error" the solution of the problem falls largely on the shoulders of the medical profession and its paramedical groups and this includes first-class leadership and strict enforcement of regulations for our pilot personnel

As we enter the zone of sonic and supersonic speeds in the upper stratosphere the demands on that human organism known

as a pilot are almost beyond the realm of imagination. What the laity and those of the medical profession like myself, who are ill versed in these matters, take for granted are the problems which you and those engaged in those disciplines, known as human factors and environmental engineering, are trying to solve.

To pinpoint my thesis that there are simple precautions that we can take to improve our safety record, let me relate three episodes that have come to light. The first appeared in a service publication in a recent letter<sup>2</sup> from the commander to a major subordinate commander.

Reference is made to — Regulation 160 109 28 August 1952 Medical Investigations of Aircraft Accident. It is noted that the provisions of this directive were not complied with in connection with this as well as other undetermined fatal accidents involving — aircraft. Since the primary reason for investigating and reporting aircraft accidents is to determine the cause, and prevent recurrence of similar types, it is requested that all base commanders under your jurisdiction be advised of the importance of insuring compliance with this regulation.

Why should situations like this arise? Are we dropping our guard?

Another report<sup>1</sup> tells of an aircraft accident in which the fundamental cause was considered to be "supervisory error."

This accident was due to lack of appropriate action prior to the accident in connection with the condition of the senior mobile control officer. He was not present for duty and had the only pair of binoculars with him so that the junior mobile control officer was unable to note an unsafe condition of the nose wheel and notify the pilot. Medical information as to the senior mobile control officer revealed that he was hospitalized on that same day with an admission diagnosis of "alcoholism chronic moderate manifested by delirium tremens stress unknown moderate predisposition with long standing history of alcoholism marked impairment." This officer was returned to flying status a few days later by his flight surgeon.

Third is an anonymous case report,<sup>11</sup> service and country not stated, in which a medical investigation of a fatal jet accident by a junior medical officer revealed as follows:

The dead pilot had trouble throughout his course of training and had just made the grade. Basically he was afraid of jet flying but was more afraid of admitting his fear; therefore he had just squeaked by. The morning of his fatal accident he arose with a bad hangover, vomited, ate no breakfast and reported for his formation flight. There was no medical check at that time. Further investigation revealed that he was frequently subject to screaming nightmares and in order to avoid these would often resort to excess alcohol and go to bed moderately drunk.

This was his usual solace at the end of his day's flying. Result was loss of life, loss of an aircraft, impaired morale of his whole outfit. The problem was solved too late by investigation by a young medical officer; it could have been prevented.

You are all aware of the two unfortunate *Comet* disasters over the Mediterranean. Do all of you know that the etiology of these disasters was solved by an extraordinarily fine exhibition of medical intelligence or detective work if you will. The medical findings were reported recently in the *Lancet*,<sup>1</sup> but unfortunately this truly beautiful and complete work was scarcely noticed in the American medical press. An almost identical account,<sup>2</sup> however, was printed in this country in a popular magazine in August, 1955. The first clue was gained by autopsies on the victims of the first accident. There it was found that all of the bodies exhibited unmistakable pathological evidence of explosive decompression. In order to verify this, animals were carried to the same height and explosively decompressed at an altitude of 30,000 feet. The pathological findings were identical. As you will recall, the fragments of the aircraft were dredged from the bottom of the Mediterranean, reconstructed, and the weakened area found above one of the windows at a seam which had blown out when the airplane reached the height of 30,000 feet.

### METHODS OF SOLUTION

What are we doing about these problems in the Department of Defense at the present time?

First, under the leadership, guidance and inspiration of Wing Commander E. Bruce Harvey, RAF, Wing Commander R. T. Lowry, RCAF, and Dr. Howard T. Karsner, advisor in medical research for the Navy, an international Joint Committee on Aviation Pathology has been established by Great Britain, Canada, and the United States.<sup>3</sup> It was my privilege to attend the first meeting which was held recently at the Armed Forces Institute of Pathology. Realizing what pathology had accomplished in furnishing the first clue as to the cause of the *Comet* failures, this committee will establish procedures for and accumulate material from the bodies of the victims in fatal accidents. This may include chemical analyses of blood or tissues, autopsies and histological examination of tissues, and medical examination of equipment and portions of the aircraft. We hope that other countries, as they may be interested, will co-operate with this committee and that our own Civil Aeronautics Administration may participate as they may be inclined to do so.

Second, for several years we have been sponsoring a program called Medical Education for National Defense, commonly known

as MEND. The origin of this program was in the committee appointed by the Association of American Medical Colleges in 1951. At first a test program was inaugurated in five medical schools, which met with a certain amount of success. Objections, however, were raised by the deans of a number of schools that attempts were being made to dictate portions of their curricula, this was considered to be unwarranted interference. In order to eliminate these objections, the program was reoriented two years ago, placed in the hands of a full time administrator and offered to ten additional schools, on their own application, with the provision that an increased number of schools would be added each year as they desired and within the means of the funds provided.

At the present time there are twenty five medical schools participating in this program. Only the faculties of the schools are involved. An organizer is appointed for each school and conferences are arranged in Washington and also in the field for the faculty members participating so that the problems of military medicine may be seen at first hand. The same faculty members do not necessarily participate in each trip but a selection is made so that each special group will be able to visit in its own discipline. Several trips or conferences are provided each year. In this manner the entire research and teaching programs of the military are made available to faculty members of our medical schools. It then rests with them how much they wish to incorporate into their courses. At the present time this program has created marked enthusiasm, as a matter of fact, more than we can keep pace with. We are already planning to include some of the dental schools and expect that some of the products of MEND will be passed on to paramedical groups through the medical and dental schools. In this manner we hope to imbue our new medical graduates with the seriousness and importance of the difficulties and various problems of necessary research which confront aviation today.

Third, the pattern of aviation is ever changing and to meet these growing demands some of our universities, both here and abroad, have instituted programs dealing with these problems. Notable among these is the well planned and complete course in aviation medicine recently instituted at the Harvard School of Public Health under Dr. Ross A. McFarland. Similar attention, though in more abbreviated form, is being given to this growing and important specialty in the College of Medicine of Ohio State University, at Johns Hopkins and at the University of California, Los Angeles, both in postgraduate and medical departments. These are in addition to the increasing growth and application of purely scientific knowledge in our great technical institutes. In addition to these there is the Flying Physicians Association, the aims of which are

interested because their job was on the flight line with aviation personnel

Whether in military or civilian aviation the flight surgeon must be a devoted, courageous, interested, first class doctor and psychologist, and also a man among his fellows. He must know and be willing to fly with each and every pilot under his charge and should have equally intimate knowledge of other members of the air crews. He must have full knowledge of them as individuals of their personalities and of their families. He must be responsible for their physical and mental fitness at all times, which includes their diet, living quarters and recreation. With aviation of today and tomorrow demanding more and more of its human component it becomes incumbent upon the doctor to assure the physical and mental fitness of those in his charge at all times. Likewise his responsibilities extend further than just the pilot and co pilot they extend to all members of the crew and also to the maintenance group who contribute to the mechanical safety of the flight. The flight surgeon is likewise responsible for a large investment of human research capital and material and the lives of passengers entrusted to the charge of the aircraft commander in flight. By flying with his pilots the doctor may discover perhaps the reasons for bravado, uncertainty and indecision. In turn he must have the courage and firmness to recommend grounding a pilot or crew member when in his opinion they are not fit to fly a particular mission. This may require real courage to stand against both pilot and commanding officer or between them.

### CIVIL AVIATION

There is a different aspect to commercial and airline flying. Whereas in military aviation the pilot is ordered to fly and may desire to fly in civilian aviation it is his right to fly according to the terms of his employment. Furthermore in civilian aviation the pilots are less under the guidance of flight surgeons than in military aviation. They and their families are a part of the community and in most instances have their own private physicians. The physician responsible for their fitness to fly, the safety of the passengers and the safety of the plane must extend his knowledge and tact in other directions. As in the military he should know each one of his pilots their personalities their families and their problems. When his suspicions are aroused that something is amiss or when the pilot is ill, he must know how to enter the family situation and cooperate with the family physician who may know nothing whatsoever about the problems of aviation medicine. Here the art and ethics of the practice of medicine enter to their highest degree. If he and the family physician agree then the problem is solved, if however a difference

of opinion arises, he must persuade the family physician of the necessity of a consultation with one or more specialists highly regarded in the profession and of unimpeachable integrity. Furthermore, on his own panel he must have available recognized specialists in the basic sciences as well as in all the specialties of clinical medicine. In the annual physical examinations or in examinations prior to the return to duty following an illness, there must be available every modern device for examination and testing. In civilian aviation this becomes particularly important now as we are about to shift to jet transports with in the next few years. It is needless for me to tell you that this will mean new training programs for the great majority of our airline pilots, not to mention the necessary changes in many of our airports and in operational concepts.

Whereas in 1954 there were slightly over thirty two million paying airline passengers, it is expected that by 1960 there will be fifty five million, with paying passenger miles almost doubled. This will mean not only additional pilots, but also additional flight surgeons.

It is good to see the increased emphasis on civil aviation medicine in the United States. The latest manifestation of this interest is the recently introduced bill (H. R. 10228), known as the Civil Aviation Medical Act of 1956, which provides for an Office of Civil Aviation Medicine within the framework of the Civil Aeronautics Administration, with a civil air surgeon and a Civil Aeronautics Medical Research Laboratory. In effect, these will be the civilian counterparts of offices and institutions found in the Armed Forces.

As planes become larger and speedier, and as the airways and airports become increasingly crowded, unless more and better controls are instituted, the fatality rate may well increase. More and more is required of the pilot. His instrument panel may grow larger and more complex. Every automatic device tends to decrease his sense of feel and his need to see. Unfortunately, however, with every automatic device there is ever present the possibility of failure, and with each added automatic check that is imposed to decrease that chance of failure, another possibility of failure arises, we can never get away from human error. It becomes our duty, therefore, to reduce both human and mechanical errors to a minimum.

### HUMAN FACTORS TEAMS

Here we come to another important factor in accomplishing this. I am sure that all of you have had difficulty at one time or another in repairing some relatively simple part of your automobile engine, maybe perhaps just replacing a nut or bolt, and

in so doing you have appreciated an inexplicable difficulty as to why that nut or bolt could not have been placed more conveniently or why perhaps did it have to be of a size or shape that could not be replaced readily. And if you have not had this experience yourself, you must have heard the cursing and muttering of various repairmen, and the suggestion that it would be a good idea if the engineers that designed the cars and their engines to catch the eyes of the public would spend more time in repairing them. So with the airplane.

When the former Research and Development Board was instituted, a committee of human relations and one of medical sciences were established. At times they overlapped and conflicted but their individual importance and cooperation were well recognized. Since then the military has developed human factors research teams,<sup>18</sup> consisting of a team captain, a flight surgeon, an anthropologist, a physiologist, a psychologist and a biophysicist. These teams work with the engineers in planning the design of airplanes with the result "that significant improvements for crew effectiveness have been accomplished in the B 47, B 52 and F 86 type aircraft through the combined efforts of the human factors teams and contractor and operational commands, at the same time that orderly integration has gone into the future systems."<sup>19</sup> Without the knowledge, thought and planning of these human factors teams it would be impossible for some of our planes to be operated with any degree of safety. They consider, for example, such problems as

- 1 The optimum number and type of crew to perform the mission and the general operational requirement
- 2 Are the altitudes required compatible with weight and space allocation from the environmental control required to provide for 100 per cent mission coverages?
- 3 For the predicted size and shape of the airplane will adequate work space be available for the crew?
- 4 Can an emergency escape configuration be provided equally to all crew members which will meet all predicted speeds, accelerations and altitudes of the aircraft?
- 5 Does the mission require of the system a human ability or skill with no previous counterpart in air operations? If additional skills will be required of the crew members what methods need be developed to provide the training in these skills?

### CONCLUSION

These are the problems that confront jointly aviation and the medical profession today. That there will be a solution, we may be sure. This cannot be done, however, either by aviation or a

new board of aviation medicine alone. It needs the interest and appreciation of these tremendous problems by the entire medical profession and the gradual institution and extension of postgraduate courses in aviation medicine similar to the recently developed in the Harvard School of Public Health. We must interest more young physicians in the problems of and satisfactions in careers in aviation medicine, and in the need for vigorous programs of preventive aviation medicine.

Human control of flight can be successful and acceptable so long as we recognize man for what he is—a human being—then engineer and operate accordingly. There is only one way to achieve fundamental safety in flight—eliminate the exposure.<sup>1</sup>

# A TECHNIC FOR MILITARY DELINQUENCY MANAGEMENT

## 1 The Problem and the Program

BRUCE L. BUSHARD *Lieutenant Colonel MC USA*  
ARNOLD W. DAHLGREN *Major MPC USAR*

A NEED exists on every Army post for a smoothly functioning approach to the evaluation, retraining, and disposition of prisoners in the post stockade. Although the post commander is assigned such responsibilities<sup>1</sup> he is not provided with the same type of special staff for their fulfillment as is the disciplinary barracks commander. This is so despite the fact that over one half of all prisoners in custody in the United States Army are under jurisdiction of post commanders.<sup>2</sup> This article describes a manner in which these missions have been accomplished at one large Army basic training center without utilizing any additional staff. It appears practicable from this experience for the Mental Hygiene Consultation Service (MHCS) to be assigned an active responsibility in the fulfillment of these missions. Active co-operation between command, the stockade, and the MHCS has made possible the achievement of unusually favorable results.

Except where specific comment to the contrary is made, the account which follows is based upon experiences and occurrences at one post during a relatively circumscribed period of time. These experiences cannot then be regarded as necessarily typical of military posts at large. It does, however, appear to us that the philosophy and techniques of operation are of value to and may be employed in other situations.

### THE PROBLEM

Confinement of personnel of the United States Army is at a rate of approximately 10 to 12 for each 1,000 persons on active duty. Of this number, 5 to 7 are in post stockades.<sup>3</sup> This constitutes then for command, a substantial sociologic and morale problem. Sixty-five operating, administrative and clerical per-

---

Washington 25 D. C. and Fort Dix N. J.

In recent years the punishment in military prisons has gone little beyond the discomforts and inconveniences involved in separation from loved ones, sexual deprivation mental (rarely very hard) labor, and lack of freedom. These uncomfortable measures are perhaps better described as annoyances than as punishments. Prisons are usually adequately heated. Beds are reasonably comfortable. Sanitation and opportunities for personal hygiene are frequently better than that to which some of the inmates have been accustomed in their former life. The "rock pile" has been replaced by industrial work with which most prisoners are familiar and which is rarely foreign to many nonprisoners in the population. The food is usually comparable in quality and quantity to that of the average citizen. In military prisons, the ration is the same as that normally issued to the soldier.<sup>12</sup> Medical care is standard and easily available while opportunities for education, socialization, and some recreation are relatively abundant. In general, in prison the lock step, the degradation, and the stony silence of former years have almost disappeared. It is unlikely that society would allow retrogression even if individuals capable of imposing it could be located. Persons capable of successful imposition of any great increase in discomfort are more likely to be found among the imprisoned than among the free population.<sup>13</sup>

In military prisons, the means of punishing prisoners who have committed offenses within prison walls are equally restricted. While the opportunity to segregate such a person and restrict the "tastiness" of his diet remains, the diet must be of adequate caloric value. Such a prisoner must be medically examined daily and cannot be physically abused.<sup>14</sup> This latter has been true at least officially since publication of *The Military Laws and Rules and Regulations for the Armies of the United States* on 1 May 1813.<sup>15</sup>

In many prisons and especially in military prisons, the attitude and behavior of custodial staffs has undergone a similar evolution. They have frequently learned to behave with the detachment and easy tolerance of social workers. They have learned to ignore verbal assault, no longer respond violently to anger and now tend only to protect themselves from actual physical assault. They look upon their charges as essentially ill and frequently demonstrate a definite skill in treating them, although their skill is one which is more likely to secure immediate compliance and co-operation than long term recovery from the delinquent state. Custodians are less obsessively security minded and are more willing to "take a chance" in the form of recommending clemency, parole and trustee status. Frequently, they encounter resistance to their ideas both in the administration

and among an angry or frightened population. They are acutely aware that while to "throw him in jail" may limit the trouble to within the prison walls it usually produces more, not less, trouble.

The study reported here is based upon a 2 1/2 year experience during which the Mental Hygiene Consultation Service became a continuous, co operating, assisting agency in a stockade operation. It provides a history of the development of this technique and proposes a *modus operandi*. Although it is not necessarily the best which might be developed, it does appear to have value. During the period of this operation, the recidivism rate has fallen, the number of disturbances has diminished, and the management of the psychiatric workload has become an easily handled flow rather than a spotty difficult problem accentuated by many emergencies.

In addition to improvement in those areas which lend themselves to statistical study, there has been a change in attitude, an improvement in motivation and morale, and an increased conviction on the part of all persons who participate that "at least something is being done." Stockade duty has become less onerous and stockade cases have ceased to appear so hopeless to examining psychiatrists.

#### HISTORY OF EVENTS LEADING TO REORGANIZATION

The Mental Hygiene Consultation Service has had, from its inception, some type of relationship to the stockade. At times various programs were established for short periods, but these rarely included the total prisoner population and never represented a real, co operative, combined effort with both command and psychiatric personnel participating. The custodial and psychiatric staffs never previously established an integrated working relationship. The programs themselves were not so much "prison psychiatry" as simply psychiatric study within prison walls. Results, therefore, had not been impressive.

The stockade itself is not usually a central concern of a military commander. Especially on a basic training post, it is a sort of "backwater," for the commander is aware that the military potential of the inmates is generally low. His time and energy are directed primarily at the training of nondelinquent individuals who present a good many problem themselves.

Persons who are confined no longer participate in basic training and are, for this reason, transferred out of their basic unit into a "replacement company." This company is also the official unit of apprehended individuals from other Army areas, deserters, and any other person who for any reason—frequently nondelin-

quent—does not participate in training. The delinquent thus ceases to be a part of an organization in which he is known. His former commander has neither responsibility for nor interest in him. The commander of the replacement company does not even see him. He is of interest to and is known by the confinement officer and his staff alone.

For MICS purposes the group might be defined as a screened collection of individuals of poor military adaptation potential. There is rarely basis for speculation on this score, little likelihood that others will argue about it, and no subtlety in the situation requiring extensive screening by MICS. It is, then, an area in which this service can operate inexpensively, depending upon normal social procedures and other agencies to do the initial screening. Further, the MICS is unable to avoid almost continuous contact with this group, for they are referred in large numbers by command to the dispensary, and for pretrial evaluation. Regardless of planning, a substantial portion of their effort is, for these reasons, directed at this group. When the prisoners are seen at MICS proper, it is not uncommon to have three or four armed guards and an equal number of prisoners sitting about the waiting room. This, to be sure, does not create an ultimately desirable experience for the nondelinquent youthful trainees who also share the waiting room. If the prisoner attempts to escape, a series of incidents will arise with which a medical installation is not prepared to cope. At times the guards insist upon exercising their right to remain with their prisoners even during the psychiatric interview and consequently make examination impossible.

In view of these factors, the stockade at this post was, in 1954, a serious problem area. The prisoners were sullen and uncooperative; the population was large, running at about 18 per 1,000 troops; and the number in disciplinary segregation was high, being at times 10.4 per 100 prisoners. Prisoners with two or more convictions accounted for 30 per cent of the population, and the number of persons with three or more convictions was substantial. Finally, individual and organized rebellion was a frequent occurrence requiring the attention of the post commander.

This culminated, in the fall of 1954, in a major disturbance in the course of which nearly all order was lost and the custodial personnel were driven from a section of the stockade. Even an effort by the commanding general himself to quell the riot was unsuccessful and he was nearly injured when rocks were thrown at him. The situation was comparable to that at San Quentin prison in 1939.<sup>4</sup>

When order was restored and the guard complement augmented, an over-all reorganization of the system of handling delinquents was directed. Certain of the custodial personnel were replaced

and a more understanding yet more firm attitude was initiated and maintained. An especially mature officer was appointed confinement officer.

Investigators were appointed to screen the population and to recommend action to be taken in individual cases. These officers found problems abounding in the population. There were persons who had as many as seven prior convictions. Some had literally never served an honorable day, and there were many more whose total honorable service fell below 10 per cent of their total service. There was no established way to expedite the elimination of narcotic addicts, alcoholics, or homosexuals whose very presence serves as a aidus for disruption, temptation, and disorder in any prison.<sup>11</sup> Although the mass of the sentenced prisoners were in confinement for minor offenses, many of them were so antisocial that a prison of less than maximum security represented more nearly a challenge for escape attempts than a reliable means for retention. They were literally "big time operators" in a confinement facility designed to restrain only the minor offender. Not only were they a direct source of disciplinary problems, but they were uncommonly capable of leading others astray and organizing concerted efforts at resistance to authority. A persistently uncooperative or delinquent trainee must be removed from his company and disciplined. Although this solves the problem on the company level, it does not do so for the post, and really represents the beginnings for the search for a solution and not the end. It became clear to the investigators that a means of handling these individuals must be developed and that it must be at a post level.

### THE PATTERN OF THE REORGANIZATION

The reorganization directed was accomplished through the establishment of three routines.

1. A post level agency was delegated the responsibility to convene a board of officers, under the provisions of an appropriate regulation to consider discharge from the service for all individuals following their third conviction by court-martial. This agency, in this case designated Post Investigations,<sup>12-14</sup> also hears other cases upon the recommendation of unit commanders, the confinement officer, or the MHCS. Through liaison with the stockade, these cases are heard not less than one month before the completion of the sentence. Processing takes place in such a way that completion of sentence and discharge from the service, if approved, are coincident. This averts the problem that arises from the fact that many of those people will not remain on the post long enough to be discharged after release from confinement. This is one of the predominant factors leading to repeated and obviously pointless and expensive trial by court-martial.

2 The confinement officer was to institute rehabilitative programs

a All employable prisoners were to be given work with which they were familiar or were to learn new, employable skills of value to the military. Their use in pointless menial labor was to be avoided. Shops were started for their employment in painting signs, repairing targets, and other menial but not degrading work. Authority to establish a shop for the repair of tentage and other such field equipment was requested and the permission was granted. This shop is under the technical supervision of the post quartermaster.<sup>19</sup>

b Mature attitudes were to be maintained. Military discipline was to be used in its constructive sense toward rehabilitation and not in a merely punitive manner, for "brutality and lax discipline go hand in hand."<sup>20 21</sup>

c A rehabilitation company was established. This is a minimum security portion of the stockade located outside of prison walls with prisoners in parolee status. A board consisting of the commanding officer of the prisoner battalion, the stockade chaplain, and a member of MICS was appointed and designated the Classification Board. Any sentenced prisoner may upon the recommendation of MICS, appear before that board. He is eligible for assignment to this company upon the recommendation of the board and upon the approval of the confinement officer. The decision is based upon the prisoner's behavior and his apparent rehabilitative potential. While in the rehabilitation company, the prisoner completes his training by being attached during appropriate hours to a unit in the proper phase of training. If he is not a trainee, he becomes available for other work.<sup>22 23 24 25</sup>

d The clemency system was enhanced. A board of officers, designated the Clemency Board, was appointed. It consists of a member of the line (usually the president), a member from The Judge Advocate General section, one from The Adjutant General section, the stockade chaplain, and a member of the MICS. This board may recommend suspension of sentence after the prisoner has served between one third and one half of his sentence. This recommendation is dependent upon his behavior, attitude, and rehabilitative potential. Appearance before the Clemency Board is not dependent upon prior assignment to the rehabilitation company.<sup>26 27-28</sup>

e The system of parole was enhanced. Prisoners who can be employed about the post are placed on parolee status when it is reasonable in the judgment of the confinement officer, to do so and they are allowed to go from their place of employment without a guard.<sup>2</sup>

f The custodial personnel remain alert for evidence of the existence of "cliques" and other organized activities in the prisoner group. Suspected leaders are placed in administrative, nonpunitive segregation. Others so segregated are suspected or admitted homosexuals, neophobes, drug addicts, noncommissioned officers, former stockade personnel, persons requiring extensive medical treatment, and others who, in the judgment of the confinement officer, represent a source for or a nidus of disruption, poor morale, or bad discipline.

g Disciplinary segregation and loss of accrued good conduct time are used when and if it becomes necessary, for any reason, to emphasize the punitive aspect of the confinement.

3 The Mental Hygiene Consultation Service enhanced and formalized its relationship to the stockade.

a All prisoners are examined within 14 days after sentence is pronounced. Pretrial examinations are prompt if and when they are requested by the commander or the defense or trial counsels.

b Persons requiring psychotherapy receive it.

c Persons, especially first offenders, likely to benefit from transfer to the rehabilitation company are referred to the Classification Board at the appropriate time.

d Appearance before the Clemency Board is recommended at the appropriate time.

e Negative recommendations are made regarding both clemency and transfer to the rehabilitation company, if, for any reason, these appear inappropriate.

f Close liaison is maintained with the confinement officer in finding mutually agreed to solutions for such problems as tantrums, suicidal gestures, suspected psychosis, evidence of organized resistance, cliques, et cetera.

g When rehabilitative efforts have been attempted and significant evidence of their lack of success has been amassed, positive recommendations for separation from the service are made.

(1) All persons whose records reveal three or more courts martial are recommended for appearance before a board of officers convened under provisions of Army Regulation 635-208<sup>23</sup> or Army Regulation 635-209<sup>24</sup>. If the examiner is of the opinion that, for some special reason, retention is in order, he may so recommend to the board. However, he does not seek to prevent the actual appearance before the board. This assures that all such cases are subject to mature command consideration.

(2) The MHCS remains conservative in recommending separation for persons with fewer than three convictions on record. It is regarded as unlikely that such persons, whatever their verbal attitudes, have been offered the full effort of rehabilitation.

(3) Any person, whatever his number of courts martial, in whose case there is reasonable evidence of homosexuality, alcoholism or drug addiction is recommended for separation under the appropriate regulation. Remission of sentence in order to expedite discharge is also recommended. Evidence of such activities is obtained not only from interview with the prisoner, but from operating personnel as well. This is not to say that mere willingness to confess such activities necessarily leads to any official action. Reasonably acceptable collateral evidence is required lest such confessions be used by great numbers merely to achieve an early release. The Command is also willing to entertain a recommendation for remission of sentence and expeditious separation from the service in other selected cases when interview or the record suggests that antisocial or organizing tendencies are beyond the capacity of the stockade to control.

The procedures authorized, then, were so constructed that command was assured that no individual would in effect get "lost" and simply stay on indefinitely neither being disposed of definitively nor rendering meaningful service. It can be seen that MHCS occupies a central position being the initiating agency in much of this program. It also soon became evident that this is the only agency which has sufficient contact with the individual to make meaningful recommendations. It is, in addition, possible for this agency to remain somewhat more objective about an individual prisoner since members of the MHCS do not have immediate responsibility for him. The reviewing authority can therefore assume that MHCS recommendations are more detached and moderate than might be those of others and for this reason, more readily place reliance upon them.

### THEORY OF OPERATION

The nature of military justice is such that persons entering confinement are rarely true first offenders. Examination of the history of an individual confinee will ordinarily reveal that his earliest offenses, if purely military, were first overlooked and later dealt with through Article 15 Uniform Code of Military Justice. His first sentence to confinement is usually suspended. In the main, the confinee has been offered both extensive counseling by various agencies and a good deal of "easy" or "gentle" disciplining. Simple advice or forgiveness has been proven to have insufficient impact to lead to improved behavior. Nor have

the usual treatment techniques ordinarily available through psychiatric agencies had a significant effect on this problem.<sup>28</sup>

From the prisoner's point of view, the situation is hopeless. He either consciously rejects his military obligation or, if he accepts it, has found some reason for not fulfilling it. He expresses the opinion that he must take care of his mother, or his wife, or the family business, or he has some other excuse. In erecting such a rationalization, he finds both an excuse for his misbehavior and a basis for anger at the Army because it does not take the necessary action to return him to his home. Angry when first confined, he is then most resistant to any type of rehabilitative effort.

From the commander's point of view, the problem is also great. This is a man who, despite frequent offers of special consideration, continues to behave in an angry, inflammatory, and insubordinate manner. His behavior has been and is such as to impugn military order and destroy discipline. Concomitantly, his impact upon the discipline and attitude of others who have not yet indulged in such florid behavior seems great. The commander, therefore, is forced to assume that if he continues to tolerate this individual's misbehavior, others will follow suit. The officer who has contact with such an individual almost certainly becomes angry, and often allows his attitude to become one in which desire to "show this guy a thing or two" becomes a factor.

Thus, by the time a soldier has been confined, both he and the individuals dealing with him have sometimes lost their perspective so completely that the situation is not an impasse. The prisoner behaves in a manner which serves him poorly, and the individuals who deal with him have allowed their emotions to control the situation to the degree that they accomplish little save to give the prisoner a good excuse for his anger.<sup>29</sup>

The outcome of this situation varies, but there is a common and readily observable pattern. This is primarily based upon the simple fact that the prisoner's anger usually causes trouble to no one but himself. He batters his head against a wall not so much made of stone as of a material that is not only unyielding but uncaring. Unless he is able to organize with others in such a way as to bring discomfort to the organization through his anger, he simply compounds his situation.<sup>30</sup> Nevertheless, some 30 per cent of prisoners indulge in some type of ill disciplined behavior during the first six weeks of confinement.

At a period that ranges ordinarily between the 30th and 60th day, the average prisoner is least recalcitrant. He is then most amenable to accepting some evidence from authority that it was his behavior which was rejected, not his person. The difference

between his attitude at that point and his attitude when he was first confined may be dramatic. If an observer is sensitive, he will note some effort on the part of the prisoner to achieve some type of nondelinquent acceptance. He sometimes must do this covertly lest he suffer rejection by his fellow prisoners if it becomes evident to them.<sup>10</sup> Nevertheless, he frequently makes some effort in this direction. This might be interpreted as the point at which authority has won the struggle. When this occurs, the prisoner is ready to comply and sometimes merely seeks some way to return to the good graces of authority in a reasonably dignified manner. If, during this period, opportunities are available for parole, clemency, or other procedures in which a degree of acceptance or at least partial trust and forgiveness are implicit, he may be moved away from his identification with delinquency and toward a more meaningful relationship with society. If such procedures are not available, he will ordinarily lapse into a type of apathy, retain or perhaps even intensify his relation with the delinquent group, and become at least, a poor risk for rehabilitation or perhaps even a severe delinquency problem within the stockade itself.

This process may then be described as one in which the prisoner has two models with which to relate and to identify. He may identify with the prisoner group and indulge in the misapprehension that delinquency is a pattern of behavior with social value. On the other hand, he may identify with the custodial group who represent "society" and attempt to emulate their more successful transactions with their environment. Although the first identification is usually with the prisoner group, many prisoners will shift their identifications from one extreme to the other in the manner described. Rehabilitation is derived, then, partly from timing the offering of clemency at the moments when the more acceptable identification is in the ascendancy.

There are, of course, many who do not follow this pattern. Many who do follow it are unable to maintain a satisfactory level of behavior for a protracted period and lapse into delinquent behavior. Statistically the results of such a plan as this are not remarkable, but the efficacy of almost any procedure in handling this type of problem is not great and one must not allow his modest statistics to discourage him.<sup>11</sup> The results of this program compare favorably with those of a long term project in a state penal system which had a 23 per cent incidence of rein carceration.<sup>12</sup> Others have ranged to as high as 60 per cent.<sup>13</sup>

The philosophy which underlies this program can be fairly simply stated. A military delinquent pursues patterns of behavior which consciously seem to him (1) to achieve his immediate desires most directly, (2) are successful in achieving a measure

of social success, and (3) cost him the least.<sup>30-32-34</sup> The treatment program is then designed to ascertain that the outcome is such that each of these aims is better achieved through conformity with normal social values than through nonconformity.<sup>35</sup>

Taking the three projected urges of the delinquent as topic headings, the program is organized as follows

1 **The Delinquent Wishes to Achieve His Immediate Desires as Directly as Possible** Psychiatry refers to the delinquent as suffering from an impulsive character disorder. He has not learned to get the things he wants out of life by careful planning, by working, or by establishing a working relationship with his community. He has not learned to achieve things by his own efforts; he impulsively grabs what he wishes with little planning and little thought of the consequences. Rather than view failure to get what he wants as an indication that he has failed to provide for himself, he blames others. Any maturity he may appear to have is a pseudo maturity in that he has not learned to be a self-sustaining individual. The delinquent then appears to be primarily intent upon short-term goals. Sometimes, on the other hand, his goals are more complex but distorted. An example of this lies in the exaggerated masculinity assumed by some delinquents. Proof of masculinity even at the cost of remarkable physical pain, though not necessarily a short-term goal, is a prime mover of these persons. In other cases, the goal may be obscure or of a profoundly unconscious origin, as in the case of the delinquent whose behavior arises out of a need for or pleasure in punishment. These more complex phenomena sometimes require more extensive types of study and treatment than is here described.<sup>34</sup>

A program for his rehabilitation need not punish his past misbehavior in order to make it sharply evident to him that such behavior has not achieved a great deal for him. Among the requirements is the maintenance of a sharp degree of objectivity on the part of individuals dealing with him. Most of the explanations given for misbehavior are not entirely truthful and some are frank lies. An occasional one is nearly reasonable. Although one cannot believe the explanations, it is of great importance that each be objectively investigated. On the one hand, the objective fact is necessary if one hopes to point out the defects in his story to a given individual. On the other hand, if but one individual has told the truth, is disbelieved, and later is able to show that his mother, for example, has realistically suffered as a result of this disbelief, all other prisoners will have received evidence testifying not to the fact that their behavior accomplishes nothing but rather that they are outcasts about whom no one cares.<sup>35</sup> They will have found a justification for

more not less, misbehavior. Only with real facts can the inappropriateness of misbehavior be brought into a palpable relief.

2 The Behavior Represents an Attempt to Secure Social Success. Nearly all people are bound together by their common interests and each receives support in his individual behavior through such an association. Although the delinquent does not form very competent relationships he seeks it from other delinquents support. Among the reasons he seeks it from other delinquents is his feeling of having been abandoned by conforming people. If the individual has no opportunity as an individual to form some type of relationship with the society he has offended his initial anger will persist and he will quickly find other delinquent individuals to whom to relate. Soon a clique or a group spirit is born in which delinquency is a socially valuable phenomenon. By its unrelenting stand, society has produced a situation which encourages delinquency. A situation has been so structured that the delinquent has no choice but to do the thing he wishes almost automatically to do anyway. That is to find others who feel as he does mutually to resist authority and consequently achieve some feeling of self worth. Under these circumstances the confinement officer finds himself not with a great many individual offenders to deal with but rather with an organized mob over which he has little control.

One attempts to avert this by de-emphasizing the notion that the prisoner is being punished for what he has done and by emphasizing that his future accomplishment depends upon the social value of his conformity. Obviously he must be provided with some kind of acceptable and reasonable dignified opportunity to conform to reasonable activities and socially acceptable restrictions. One must also ascertain that the individual prisoner has more to gain from negotiating with society as an individual than as part of a group. If whatever he does the individual sees no possibility of achieving acceptance he will tend to join a delinquent group. If however, his problem is dealt with in an individual manner and he may get clemency or other special consideration only as an individual the formation of groups will have no real value to the individual and to that degree will be discouraged. Such a program at this must, then be carefully individualized.

3 The Delinquent Seeks to Achieve the End He Feels is Least Cost to Himself. In this regard a punitive aspect of the situation is preserved. It is an economic truism that it is at least potentially more expensive or perhaps more uncomfortable to fail to conform than to conform. Humans will rush to what they think is the least costly type of behavior.

The operation of such a program must be carried out in such a way that if an individual cannot be dissuaded from delinquency, at least it costs him more than conformity to society's demands would. The recalcitrant prisoner must find that he remains behind after the more conforming person has left. No particular behavior pattern which is delinquent and which is designed, at little cost to the individual, simply to force the hands of authority can be allowed to succeed. The most frequently encountered of such activities are suicidal gestures, temper tantrums, and hunger strikes. In such cases, prompt determination must be made as to whether such behavior is the product of a frankly psychotic mental disease. Immediate hospitalization is necessary if such mental disease is present. If not, both the psychiatrist and the stockade staff must have the courage and strength of purpose to deny the prisoner's bid for special attention even though, in the end, such behavior usually will influence one toward a final decision recommending discharge from the service. If and when the individual is to be granted the attainment of the goals which motivated such behavior, this success must come only after the behavior has been abandoned. The hunger striker who returns to the mess hall and the suicide gesturer who is sent back to work serve as marked evidence that such behavior is not valuable. To accord such individuals special treatment tends to enhance the probability of whole epidemics of such behavior. Cooperation between psychiatric and stockade personnel in carrying out this kind of procedure is essential. It might be easier for all concerned to deal differently with an isolated case, but one is then at a loss to know what to do with 10 of them. During the period reported on, there was not a single case of successful suicide in the stockade, even though the population always included two or three people who periodically threatened it.

This program is designed, then, to promote group forces which tend to press individuals toward nondelinquent patterns of behavior. This is accomplished through providing the prisoner group with only that information on which they can predict what will occur if they conform with normal social attitudes and behavior patterns. They must know that if they conform in a proper manner, opportunities exist for eventual restoration to a satisfactory position in society. They must not be able to predict what delinquent singular things they can do or what frightening or threatening statements they can make to secure an early release, special attention, or disorganization of the administration. They are sensitive to ways in which they can remain delinquent and will use these ways if they sense a weakness in the system. They will soon sense the existence of a too rigid policy which, for example, requires that all individuals given to a certain act

be discharged from the service immediately. They will then have information available as to the price they must pay to get out of the stockade or the Army. To deal with each such case on its own merits, tends to produce a sufficiently varied pattern of administrative response so that such an outcome can be avoided and the prisoner group can be deprived of knowledge of such policies even if they exist.

### SCOLIOSIS

\*Early recognition of scoliosis is possible if the back is examined with the patient bending forward. This should be part of every physical examination in children. Deformity increases most during the period of rapid vertebral growth from 11 to 15 years of age unless it is corrected. The severity of scoliosis is expressed in degrees of angular measure as determined on the roentgenogram. If it exceeds 30 degrees complete restoration is no longer likely to be achieved because the average amount of correction obtained by traction, body casts, and surgical fusion of the affected vertebrae is about 25 degrees. The use of a localizer cast makes it possible to keep the patient ambulatory all the time except for the 7 to 10 days after surgery. The total period of immobilization of the patient's back after operation is 8 to 10 months."

## Clinicopathologic Conference

U S Naval Hospital Corona Calif

### ABDOMINAL PAIN ANEMIA AND SUDDEN DEATH

**Summary of Clinical History** A 26 year old married white woman had nausea, vomiting, and lower abdominal pain in July 1955 who was told by a physician that she had a bad tubo and needed an operation. She refused the operation, however, and recovered until the onset of the illness requiring her first admission to this hospital.

#### FIRST ADMISSION

The patient was first admitted to this hospital on 14 October 1955. For five days, following a normal menstrual period, she had been experiencing nausea, vomiting, and right lower abdominal pain of increasing severity, which radiated to the back. For two days prior to admission, she had a cough productive of one-half cup of sputum per day. No diarrhea or constipation were present. There was no history of recent sexual intercourse, her husband having been overseas for several months.

At the age of six years she had diphtheria and a tracheostomy. At eight years of age she was suspected of having poliomyelitis. For many years as a child she had frequent nose bleeds, but none in recent years. For several years she had had frequent sore throats and bouts of coughing productive of yellowish sputum. The patient was a heavy smoker. Four years prior to this

Capt Alton C. Abernethy MC, USN Commanding Officer

hospital admission she received a bullet wound of the liver requiring laparotomy, from which she completely recovered. The patient has one child four years of age and has had no miscarriages.

**Physical Examination** The patient was moderately well nourished and of average development. Her blood pressure was 116/68 mm Hg, temperature, 99.6° F, pulse, 88 per min, and respirations, 20 per min. There was increased pigmentation of the skin and mucosa. The patient was a brunette. The nasal and pharyngeal mucosa were congested. The heart, lungs, and breasts were normal. The abdomen was soft, there was tenderness without spasm in the lower abdomen, but none in the flanks. On bimanual pelvic examination there was tenderness, more so on the right side. The cervix was normal, the uterus was small, retroflexed, and in the midline. One examiner noted pain on motion of the cervix, and thickening and tenderness of the sacrouterine ligaments and both adnexa, but no definite masses.

**Laboratory Studies** The urine was normal and had a specific gravity of 1.026. A white blood cell count was 13,150 per  $\mu$ l, with 3 per cent band forms, 71 per cent neutrophils, and 26 per cent lymphocytes. Hemoglobin was 12.8 grams per 100 ml, hematocrit, 37 ml per 100 ml, and red blood cell count, 3,920,000 per  $\mu$ l. The red blood cell indices were mean corpuscular volume (MCV), 99 cu  $\mu$ , mean corpuscular hemoglobin (MCH), 32  $\mu$ g, and mean corpuscular hemoglobin concentration (MCHC), 34 per cent. An antistreptolysin titer was 1:50. A roentgenogram of the abdomen showed normal findings and one of the chest revealed clear lung fields and a cardiac silhouette of normal size and position. An electrocardiogram disclosed normal findings.

**Course in Hospital** The patient was treated with penicillin and streptomycin sulfate. On 15 October she was afebrile and abdominal tenderness was minimal, with no rebound or guarding. On 16 October her abdomen was not tender and she felt well. On 17 October she complained of right suprapubic pain and stated, "The bones of my legs hurt and I can't move on waking in the morning." On 23 October she was afebrile, her abdomen was not tender, and she felt well. Pelvic examination revealed tenderness of the right fallopian tube. She was discharged on the ninth hospital day.

#### FINAL ADMISSION

On 29 October 1955, she returned to the outpatient clinic complaining of shortness of breath, nausea, vomiting, and multiple aches and pains. The shortness of breath was present at rest as well as on exertion. Physical examination of the chest disclosed normal findings except for hyperventilation. Blood pro-

sure was 104/76 mm Hg and pulse, 120 per min. Examination of the abdomen revealed normal findings. It was thought that her symptoms were on an emotional basis and 0.1 mg of Serpasil (brand of reserpine) three times daily was prescribed. On 1 November a neighbor called the hospital to say that the patient was very sick, and she was readmitted.

The patient stated that following discharge from the hospital she had done well for one week. She then began to be short of breath, had fainting spells, and bouts of nausea, vomiting, diarrhea, and abdominal and pelvic pain. She had also become apprehensive. Sometime in the preceding three days she had fainted in her bathroom, striking the left side of her face against the tile. She had some burning on urination, and noted the passage of bright red blood from the vagina when voiding or defecating. She denied the ingestion of any poisons or drugs other than Serpasil.

**Physical Examination.** The patient was acutely ill, pale, markedly dehydrated, slightly cyanotic, and breathing rapidly. Her temperature was 96.4° F rectally, pulse, 80 per min, respirations, 30 per min, and blood pressure, 70/40 mm Hg. There were ecchymoses in the left orbital area and over the right knee. No petechiae were present. The mouth was dry, the tongue was coated and brown, there was no acetone odor to the breath, and no lead line or mucosal burns. The neck was supple. No enlarged lymph nodes were present. The lungs and heart were normal. The abdomen was soft and flat. There was generalized abdominal tenderness on light palpation, more marked in the epigastrium and right upper quadrant. The liver edge was palpable 2 to 3 fingersbreadth below the right costal margin. The patient complained of pain in the knees on movement, and of abdominal pain on movement of the thighs, especially the right. On pelvic examination, the uterus and adnexa were normal and there was little tenderness. Tendon reflexes were somewhat hyperactive, but equal, there were no abnormal reflexes. The left ocular fundus was normal, but the right was not visualized. One observer thought there was slight icterus.

**Laboratory Studies.** The urine was amber and acid, with a specific gravity of 1.022, albumin, 3 plus, normal sugar, and 10 to 15 coarsely granular casts and 8 to 10 white blood cells per high power field. A red blood cell count was 2,540,000 per  $\mu$ l, hemoglobin, 9 grams per 100 ml, and hematocrit, 24 ml per 100 ml. Red blood cell indices were MCV, 94 cu  $\mu$ , MCH, 35  $\mu$ g, and MCHC, 37.5 per cent. A white blood cell count (including nucleated red cells) was 50,000 with 57 per cent neutrophils, 5 per cent band forms, 5 per cent metamyelocytes, 1 per cent myelocytes, 30 per cent lymphocytes, and 1 per cent monocytes. The smear showed 44 normoblasts per 100 white cells. Platelet

count was 300,000 per  $\mu$ l. Coagulation time of venous blood was 3 min 15 sec. The prothrombin time of the patient was 27 sec, control 15 sec. Serum bilirubin was 1 mg direct, 1.0 mg per 100 ml, 3.0 mg direct, 1.6 mg per 100 ml, and 3.0 min total, 4.0 mg per 100 ml.

**Course in Hospital.** The patient was placed in an oxygen tent and 1,000 ml of 5 per cent dextrose in water was given by vein. Her blood type was O positive. A transfusion of cross matched, O positive blood was started at 1810 hours, after the blood specimen for laboratory examinations had been obtained. At 1830, after 100 ml had been administered, the patient screamed for help and went into profound collapse. She was pronounced dead at 1840.

### DISCUSSION

**Doctor Hill:** From a study of the protocol it appears that the patient definitely had a gynecologic problem, and while it may not be the major one, it was a contributing factor in her illness.

The onset of such symptoms following menses often suggests pelvic inflammation, and the history of previous medical examinations further strengthens such a hypothesis. Tubal abortion can mimic most any syndrome of pelvic origin and must be strongly considered despite the menstrual and absence of sexual contact history. The temperature of 99.6° could be present in various types of tubal disease, and the rather negative findings on pelvic examination do not rule out tubal abortion, though they eliminate any marked inflammatory process. The laboratory findings on the first admission are not indicative of any specific abnormality.

Apparently the process responded promptly to antibiotics only to recur six days after discharge from the hospital. The symptoms described at the outpatient visit, plus the rapid pulse, strongly suggest oxygen want; it may have been hemorrhagic in origin, such as is seen with reactivation of tubal abortion when the process is temporarily stayed by adjacent visceral adherence, omental attachment, and the like.

It would have been wiser to readmit the patient to the hospital for further observation and treatment at this point; a posterior colpotomy might have been indicated.

At the second admission to the hospital the record shows that the patient evidently had urgency and had fainted in the bathroom. She had pelvic and abdominal pain, nausea, vomiting, and diarrhea. This to me forcefully intimates pelvic bleeding; a tubal abortion will give almost the identical picture as portrayed. The physical examination elicited some findings characteristic of internal hemorrhage, the gen-

eralized abdominal tenderness plus rather negative pelvic observations by no means eliminated the possibility of tubal bleeding.

The liver enlargement plus marked aberrations of laboratory tests indicate systemic disease whose nature the medical service will attempt to fathom. From the gynecic viewpoint, I am strongly inclined toward the diagnosis of tubal disease and most especially toward a tubal abortion in some phase.

Doctor Fox. In discussing this case I plan to concentrate on the anemia. First, let's review the findings in her blood. During her first admission on 15 October 1955, she had slight leukocytosis with slight increase in the neutrophils. There was a borderline value for the hematocrit. The cell indices were MCV, 99; MCH, 32 and MCHC 34. These values are within the limits of laboratory error. On the second admission, 1 November 1955, she had moderate anemia, the hemoglobin having dropped from 12.3 to 9 grams per 100 ml and the hematocrit from 37 to 24 ml per 100 ml. The indices were MCV 94 MCH 35 and MCHC 37.5. These values were essentially unchanged from the previous ones. In addition the white blood cell count was elevated to 50,000 per  $\mu$ l. 44 per cent of these cells were normoblasts leaving an actual leukocyte count of 28,000. Differential showed 57 per cent neutrophils, 3 per cent bands, 5 per cent juveniles and 1 per cent myelocytes, a total of 67 per cent myeloid cells and a definite shift to the left with immature cells. The platelets were normal. The anemia was moderate in degree and was normocytic and normochromic. Other laboratory tests of immediate concern were the coagulation time, which normal and the prothrombin time which was moderately prolonged, not in the range to cause bleeding. The serum bilirubin was 2.4 per 100 ml indirect, 1.6 mg per 100 ml direct at 30 min. In addition the patient had hepatomegaly but her spleen was not palpable.

I want to start with the consideration of various types of anemias and discuss this case from the standpoint of each of these types. There are four chief types of anemia: (1) deficiency, (2) blood loss, (3) increased destruction, and (4) decreased production of blood cells. *Starting with the first*, I think we can eliminate deficiency as a cause in this case. Iron deficiency causes a microcytic hypochromic anemia whereas  $B_{12}$  and folic acid deficiencies cause a macrocytic anemia. Other causes of deficiency anemia are protein deficiency and possibly vitamin C deficiency, neither of which seems applicable in this case. Experimentally anemia has been produced in animals by deficiency of pyridoxine and other B vitamins but clinically this has not been demonstrated.

Next we can consider anemia due to an acute blood loss. I believe we can make out a good case for this type of anemia in this patient. First there is a history of blood loss from the vagina. The description does not sound like enough blood loss to account for the whole pic-

ture Internal hemorrhage, particularly intraperitoneal hemorrhage, could explain a good deal. The leukocytosis, presence of immature myeloid cells, normal platelet count, and normal clotting time all fit in this category. Indirect bilirubinemia is seen in hemorrhage into the serous cavities due to absorption of the blood pigments. However, the percentage of normoblasts is out of proportion to the degree of anemia. It is my impression that in acute posthemorrhagic anemia the more usual finding is reticulocytosis with perhaps a few normoblasts. Other points against a blood loss anemia are the prolonged prothrombin time and the hepatomegaly.

The third type of anemia is that due to increased destruction of red cells. We have two subgroups here, the first due to intracorpuseular causes. Under this we can list sickle cell anemia, hemoglobin-C disease, thalassemia, familial hemolytic jaundice, nocturnal hemoglobinuria, and others of the abnormal hemoglobin diseases. The patient had no past or family history suggesting any of these and there was no comment as to the presence of spherocytes, sickle cells, or target cells in her blood smear. The second subgroup is the extracorpuseular causes of increased destruction. Under this category come the acquired hemolytic anemias. First we have those acute anemias due to immune body reactions. These include transfusion reactions, the anti-Rh and anti-Kell, and other mixed group transfusion reactions. There are then the cold, warm, and blocking antibody agglutinins, and finally the cold hemolysins causing cold hemoglobinuria.

The second category of hemolytic anemia is the idiopathic hemolytic anemias without demonstrable hemolysins or agglutinins. A third type is secondary or symptomatic hemolytic anemia. This type includes hemolytic anemias secondary to known primary disease. This is most often seen in association with Hodgkin's disease, leukemia, other malignant lymphomas, lupus erythematosus, carcinomatosis, lymphomas, or liver disease.

In the fourth group of hemolytic anemias are those due to infections, in this group we can include malaria, which on a world wide basis is probably the largest cause of hemolytic anemia, and septicemia, especially that due to infection with clostridia, streptococci, and *Escherichia coli*. Finally there is the group of hemolytic anemias caused by chemicals, physical trauma, particularly heat, and vegetable and animal poisons.

In this whole group of hemolytic anemias I think we can eliminate many without further discussion. The possibilities that remain are an acute hemolytic anemia with or without hemolysins or agglutinins, and either idiopathic or secondary. We do not know whether the patient had agglutinins, as no tests were performed for them. It would have been interesting to do tests for cold, warm, and acid agglutinins and to do a Coombs test. I think we can make out a good case for this type of anemia. The indirect bilirubinemia, leukocytosis, immature

myeloid cells normal platelet count and normal clotting time all are compatible

In addition, many items in this patient's history could be due in whole or in part to hemolytic anemia. The pain in her abdomen, pelvis, and extremities, the nausea and vomiting, shock, weakness, dyspnea, and fainting all fit. The lack of splenomegaly is slightly unusual. The prolonged prothrombin time also does not fit a hemolytic anemia. The most important single finding against hemolytic anemia is the number of normoblasts. The same argument holds in this instance as against blood loss anemia. I would expect reticulocytes and a few normoblasts but not 44 per cent normoblasts especially in an anemia which is only moderate in degree.

Considering the possible primary disease with which an acute hemolytic anemia might be associated there is leukemia, and in favor of this we have an elevated white blood cell count but no other real evidence. Hodgkin's disease and malignant lymphoma are possibilities but we have no positive evidence. Liver disease is a possibility, and the patient did have a history of a bullet wound of her liver. However, I don't believe there is any backing in the history for a diagnosis of liver disease. Infections including malaria and septicemia seem unlikely. It is true that the first admission seemed definitely associated with infection in her pelvis but the terminal picture was not that of a septicemia. In regard to lupus erythematosus one point in favor of this diagnosis is that the patient had a puzzling illness which caused her death. However, there is no specific evidence for lupus.

The fourth large category of anemia is that due to decreased production of red cells. The first subgroup here is that of congenital hereditary types under this heading come many of the diseases previously discussed as hemolytic anemias. These include sickle cell anemia, thalassemia, and other hemoglobin diseases. There is decreased production as well as hemolysis in these conditions. Secondly, there is the acquired group of anemias due to decreased production. Again we can list the possible causes of an acquired infection of this type. Infections are a possibility. In every acute infection of any degree of severity there is probably a certain amount of bone marrow depression. However, this does not account for the normoblasts and the immature white cells. Chronic disease such as nephritis can cause an anemia of this type but there is no evidence for nephritis in this case. Terminally the patient had some albuminuria and casts but on her previous admission only two weeks before she had had a normal urinalysis. Other causes are lead intoxication, x-ray irradiation, and chemical toxins. None of these seems operative in this case.

Endocrine disorders such as myxedema and Addison's disease can cause anemia due to decreased production of cells. In consider-

ing Addison's disease it is interesting to note that on the patient's first admission she was found to have increased pigmentation of her skin and mucosa. Then on her final admission she was in a state of shock and prostration which rapidly led to her death. It is interesting to speculate that possibly her terminal illness may have been Addisonian crisis. If her primary illness was tuberculous salpingitis, her Addison's disease could well have had a related cause, this could account for many aspects of the picture. However, I don't believe that Addison's disease explains her anemia, particularly the presence of normoblasts.

Finally, the last category of anemia due to decreased production is myelophthytic anemia. The causes of myelophthytic anemia include leukemia, Hodgkin's disease, and malignant lymphoma, all of which we have mentioned previously and excluded. Myelofibrosis or sclerosis is a possible cause of this type of anemia. It would explain the anemia itself very well but would not, I believe, explain the rest of the history and the laboratory findings. The last possibility is that of malignancy with metastases to the bone marrow. I believe we can make out a very strong case indeed for this type of anemia. The blood picture fits to a "T". There is a leukemoid reaction which has also been called leukoerythroblastosis. There is an elevated white blood cell count with immature myeloid cells. The white count in a leukemoid reaction is not necessarily elevated but the presence of immature cells is constant. The presence of the normoblasts is characteristic. The platelets may be low or may be normal, as they were in this case. Frequently there is pancytopenia as a result of a myelophthytic anemia, but the leukemoid picture is a frequent one. Other points in the case which could fit this type of anemia are the pain which could have been bone pain due to metastases, the hepatomegaly, and prolonged prothrombin time and bilirubinemia which could be explained by liver metastases. The abdominal pain with motion of the legs suggests involvement of the retroperitoneal areas and the psoas muscle by tumor. And again the possibility of Addison's disease arises here due to invasion of the adrenals by tumor.

So to explain the anemia we have three main possibilities: (1) blood loss, (2) hemolytic anemia, and (3) myelophthytic anemia due to metastatic carcinoma. I think the patient probably has all three. There is a definite history of blood loss. Recent studies have shown that there probably is increased red blood cell destruction in most cases of anemia associated with metastatic carcinoma, even though it may not be demonstrable with the usual methods. And finally the third possibility, that of myelophthytic anemia due to metastatic carcinoma, I believe is the chief cause of this patient's anemia.

We then should consider the cause of her sudden death. She died shortly after the start of a transfusion. This immediately suggests that the transfusion had something to do with her death. However, when we analyze this we find that it is rather unlikely. A hemolytic

transfusion reaction which leads to the patient's death usually causes death by anuria due to lower nephron nephrosis. The death is a slow one and not an abrupt one as in this case. A second possibility of causation of her sudden death is embolism and I think this is a very probable cause. The embolus could either have been a tumor embolus or from a venous thrombosis in the pelvis or the legs. I think the suddenness of her death is in favor of this. Bleeding as a cause of her sudden death is a possibility. This would have to be internal and I do not think it can be excluded.

In selecting the site of the primary carcinoma, which we are postulating, we must consider the types of carcinoma which tend to metastasize to the bone. These include carcinoma of the breast, thyroid, stomach, kidneys, bronchus, and colon. An undetected primary lesion in any of these sites is a possibility. However, the patient's symptoms all pointed to her pelvis and her genitourinary tract. Carcinoma of the kidney is a possibility. Carcinoma of the cervix, I think, is ruled out by the physical examination. Carcinoma of the fundus of the uterus, carcinoma of the fallopian tube, and carcinoma of the ovary are all possibilities. She was noted to have tenderness of the right fallopian tube, so I will place the site of the primary there.

In summary then she had carcinoma arising in her genital organs, probably the right fallopian tube, with metastases to the liver and bone marrow. She had myelophthitic anemia due to bone marrow metastases. The terminal event was probably pulmonary embolism from a pelvic vein thrombosis.

Dr Hill's diagnosis

Tubal abortion

Dr Fox's diagnoses

- 1 Carcinoma of right fallopian tube, with metastases to liver and bone marrow
- 2 Myelophthitic anemia
- 3 Pulmonary embolism from pelvic venous thrombosis

#### PATHOLOGIC FINDINGS

Doctor Fuller. Post mortem examination of the body revealed skin ecchymoses around the left eye, over the right knee and right leg on the left buttock, and around needle puncture marks in the arms. There was icterus of the conjunctivas, the endothelium of the heart and blood vessels was stained pink. Blood was present in the endometrial cavity and vagina. A moderate amount of fatty material was present in the lower small intestine and colon. There were numerous small serosal hemorrhages. A few fibrous adhesions were located in the right upper abdomen around the liver and in the lower portion of

the right pleural cavity. Liver and spleen were slightly enlarged, the former weighing 1,850 grams and the latter 350 grams. The lungs were moderately congested.

Except for the right fallopian tube, the gross appearance of the viscera and body cavities was otherwise normal. In the right fallopian tube at the junction of its proximal and middle thirds, was a solid ovoid mass, 2 cm in length and covered by intact serosa and attenuated muscularis (fig. 1A). Its cut surface was firm and gray, and it lay within the lumen of the tube, being attached to the mucosa by a broad base. The red hematopoietic marrow of the lumbar vertebral bodies was largely replaced by nodular gray tissue (fig. 1B).

Figure 1 (A) Right fallopian tube containing carcinoma at junction of proximal and middle thirds. (B) Lumbar vertebral body containing nodular metastatic tumor. (Photograph by Jim England)

Microscopic examination revealed papillary adenocarcinoma of the right fallopian tube (fig. 2) with widespread hematogenic dissemination. Plugging of pulmonary arteries and alveolar capillaries by embolic tumor cells was particularly widespread (figs. 3 and 4). Intravascular tumor emboli were noted in most of the parenchymatous organs. There was massive replacement of hematopoietic tissue by tumor in sections of lumbar vertebral marrow (fig. 5). Extramedullary hematopoiesis was noted in the spleen. The uterine cavity was lined by menstrual endometrium, as would be expected with the usual cycle of 28 to 30 days.

Figure 5. Photomicrograph of lumbar vertebral body of hematopoietic marrow by metastatic tumor (X 165) (Courtesy of the Armed Forces Institute of Pathology)

## Pathologic diagnoses

- 1 Adenocarcinoma, right fallopian tube, with metastases to bone marrow, liver, lungs, spleen, hypophysis, adrenals, and ovaries
- 2 Myelophthisis and hemolytic anemia

## COMMENT

Doctor Kuehn \* Anemia is one of the common manifestations of cancer and other neoplastic diseases. The incidence of anemia in patients with cancer obviously depends in large part on the type and stage of progression of the neoplastic process. In general, anemia is usually associated with the more advanced stages of the disease, and even then is most frequently mild or moderate in degree. Symptoms due to anemia, however, may be the presenting complaints of the patient with cancer, and the anemia may be severe.

We may classify anemias occurring in cancer patients as follows: (1) iron deficiency anemia, (2) megaloblastic anemia, (3) myelophthisic anemia, (4) hemolytic anemia, and (5) myelopathic anemia.

1 *Iron deficiency anemia* Iron deficiency anemia caused by chronic blood loss from ulcerative neoplastic lesions, particularly of the gastrointestinal tract, is commonplace among patients with cancer. The usual findings are characteristic hypochromia, microcytosis, variation in size and shape of the mature erythrocytes, normoblastic hyperplasia of the bone marrow, and a low serum iron.

2 *Megaloblastic anemia* While macrocytosis may be a feature of the hemolytic or myelophthisic anemias associated with neoplastic disease, the association of a truly megaloblastic anemia with cancer is unusual. It is virtually limited to gastric carcinoma. The high incidence of gastric carcinoma in patients who have had pernicious anemia is well known.

3 *Myelophthisic anemia* While the anemia associated with disseminated cancer cannot usually be ascribed to replacement of the bone marrow by the neoplastic process and its accompanying fibrosis, such replacement does occasionally occur and gives rise to a distinctive hematologic picture which is indistinguishable from that observed with bone marrow replacement due to other causes. The distinctive characteristic of this type of anemia is the presence of immature granulocytes and of nucleated erythrocytes in the peripheral circulation. These are claimed to arise from the foci of extramedullary hematopoiesis. The extent of bony involvement varies from minimal

to extensive, without apparent relation to the hematologic manifestations of myelophthisis. The hematologic abnormality appears unrelated to the type of osseous metastasis, that is, either osteoblastic or osteolytic, or both, or to the duration of the lesions. The nonnucleated erythrocytes in the peripheral blood are normocytic or slightly macrocytic. They show polychromasia, basophilic stippling, and variation in size. A moderate reticulocytosis is common. Because of the reticulocytosis, the frequent splenomegaly, and the occasional presence of jaundice, the possibility has been suggested that the anemia may be hemolytic in nature. The usual tests for red cell and serologic autoantibodies are almost invariably negative. Erythrocyte survival studies, however, do show a decreased survival of autogenous and homologous red cells, but it is not of such a degree as to account entirely for the anemia. Consequently the deficit in erythropoiesis appears to be of primary importance. This deficit seems reasonably ascribable to marrow failure since bone marrow aspirations usually yield very scanty, hypocellular material.

4 *Hemolytic anemia*. Classical, acquired hemolytic anemia, with acholuric jaundice, marked reticulocytosis, spherocytosis, and auto-sensitization of the red cells is relatively common in chronic lymphatic leukemia and the malignant lymphomas. It has also been described in ovarian teratomas, but such an anemia is rare in the carcinomatous diseases. Only a dozen or so cases are reported in the literature. Almost all have been observed in association with widespread bone marrow metastases. The primary site of cancer has usually been the stomach, but it has also been reported for the bronchus, pancreas and large intestine. In several of the cases the manifestations of hemolytic anemia were so prominent that the patients were considered to have idiopathic acquired hemolytic anemia before a diagnosis of cancer was established. The relationship of this syndrome to the more usual myelophthisic anemias is not clear. Both have in common the finding of cancer cells invading the bone marrow, and in both there is an increase in the rate of red blood cell destruction. In hemolytic anemia, however, the evidences of increased destruction are much more obvious, and there are clear evidences of considerably increased erythrocyte production, as manifested by reticulocytosis, which is usually well above 10 per cent and may be as high as 80 per cent, and by the normoblastic hypercellularity of the bone marrow.

The pathogenesis of this hemolytic anemia remains speculative. In only one recorded case was there evidence of auto-sensitization or serologic agglutination, and even this cannot be well established, since the apparent auto-sensitization may have been the consequence of transfusion. It has been suggested by Naugle<sup>2</sup> that the stagnation of blood in marrow sinusoids be

hind tumor emboli might lead to "hemorrhagic extravasations" within the marrow and thus contribute to an apparent hemolytic anemia. It has been reported by Gross<sup>7</sup> that extracts of carcinomatous tissue may lyse homologous erythrocytes. It is conceivable, then, that stagnation of blood in the sinusoids might expose the red cells for more or less prolonged periods to the lysins associated with the cancer cells, and thus lead to intense hemolysis.

**5 Myelopathic anemia** When the preceding types of anemia associated with cancer are eliminated, there are still large numbers of patients with cancer who have an otherwise unexplained anemia. The majority of these patients do not have bone marrow metastases. It is characteristic of this type of anemia that it is mild or moderate in degree. The erythrocytes are normochromic, or occasionally slightly microcytic and hypochromic. Reticulocytosis is within normal range or slightly elevated. The bone marrow appears normally cellular, or it may show a mild normoblastic hyperplasia.

As in the anemia of infection, with which the myelopathic anemia or cancer is apparently identical, there appears to be an abnormal metabolism of iron. Serum iron levels tend to be low, as do the concentrations of iron binding globulin, yet the iron stores of the body are higher than normal. The mechanism of the diversion of iron from the plasma to the reticulocadothermal system is not understood. Recent studies in the last few years

have shown a decreased survival of normal erythrocytes transfused into patients with this anemia. Other studies indicate that the increased rate of erythrocyte destruction is due to premature aging of the normal erythrocytes in the patient's circulation rather than to some serologic or tissue factor destroying red cells at random. Regardless of the mechanism of red cell destruction, there are apparently other factors occurring in this anemia. Studies indicate that in patients with this type of anemia, the bone marrow does not compensate to the extent that the normal bone marrow can.

**Doctor Lucas \*** In less than 5 per cent of reported cases of carcinoma of the fallopian tube has a correct preoperative diagnosis been made.<sup>4</sup> Pain, often colicky in nature, and localized to one lower abdominal quadrant, is usually present. Rapid distention of the tubal wall by tumor has been postulated as the cause of the early occurrence of pain. Reported survival rates have in general been poor, varying between 0 and 40 per cent.

## SIMPLE IDEAS PRODUCE GREAT DISCOVERIES

The clinician, as he looks with some envy at the beautiful, peaceful laboratories of his colleagues in the basic sciences should recall the lowly origin of many of the most important medical discoveries. Although Jenner was the first to demonstrate the potentialities of vaccination of smallpox, the procedure originated in some prehistoric and devoid of gleaming laboratories and scientific patterns. Withering listened to the tales of an old woman's secret remedy for dropsy, identified foxglove, and thus discovered digitalis. Many years later, Vogel noted that guinea pigs less readily churning the urinary output of patients, regularly recorded an increase after the administration of an organic mercurial to syphilitic patients; thus was the clue in effect of the mercurial drugs discovered. Sir James Mackenzie studied the patients who came to him and wrote his classic treatise on heart disease. Lord Liston paid no attention to the importance of the discoveries of Pasteur, instituted a laboratory in the operating room and founded modern aseptic surgery. George Minor and William Mayo fed liver to guinea pigs with pernicious anemia, made a completely new discovery, recorded in case reports, won the Nobel Prize, and added many years to the lives of world cancer victims. The methods used by these men were all commonplace ideas were present, ideas arising in groups and individuals, with persistence and perseverance, the clinical day-by-day can help to extend our knowledge and push back the borders of the unknown.

## SERVICE ARTICLES

# ARE WE OVERLOOKING THE EFFECTS OF COMBAT EXPERIENCE IN SOME OF OUR PSYCHIATRIC CASES?

CHARLES S. MULLIN *Captain MC USN*

**I**N A RECENT article by McMullin there is the following intriguing statement

"A rather striking phenomenon observed in our [naval psychiatric] hospitals during these past several years (1951 through 1954) has been the rarity of combat neuroses and the infrequency of any type of psychiatric disorder that could be correlated with combat situations. Those of us who saw hundreds of such cases in World War II now are hard pressed to find even one or two cases for teaching purposes."

Can it be that we are overlooking the importance of combat experiences in the initiation and perpetuation of psychiatric disability as seen in our military practice? There does appear to be a curious diagnostic blind spot, particularly among the more "analytically oriented" of our fraternity, in considering the possible influence of combat experiences in determining the development of a psychiatric disorder where the combat experience may have occurred many years before.

I have tried to be disciplined in my evaluation of what constitutes evidence of the psychotraumatic effects of combat. If a man has been exposed to intimate combat experience and thereafter intermittently or continuously has suffered a definite personality change characterized by such manifestations as depressive ruminations about these experiences, acoustic hypersensitivity, more or less severe startle reaction to sudden noises—particularly those noises resembling the sound of gunfire, explosions, or cetera—a phobic avoidance of stimuli suggestive of the combat situation, nightmares of combat scenes, marked irritability often associated with explosive rages and a general reduction of executive effectiveness, then some respect should be shown to the possibility that the traumatic effects of the experiences themselves are still operating. The fact that

---

From U S Naval Hospital Camp Pendler in Calif

over the years a complicated role in the development of the secondary dependent conflict has been revealed, and the obscure the traumatic "core" symptoms.

The cases of three patients who happened to be in my own small service at the same time illustrate the problem. They were three young men, officers unknown to one another, who had been admitted with varying presenting complaints and whose cases had been worked up in great detail, each by a different psychiatrist. In each instance the psychiatrist was competent in one or more of the had 8 years of experience in creating serious alienation and importance of combat experiences in the past, but the importance of adjustment was totally missed in each of the cases. In fact in hospitalization. In two instances, the psychiatrists, by their combat experiences were important in the past, but the importance by our psychiatric social service workers who happened to take an additional history. In the other instance, while the psychiatrist to assist the psychiatrist in charge of the case to understand the origins of the patient's illness. I concluded that the psychiatric that combat experiences were important.

Understanding the role of traumatic factors in the development only to diagnosis, but also, very empirically, to a logical treatment.

Case 1 A sergeant was admitted because of "nervousness" as well as with alcoholism and unauthorized absences, flu periods, depression with suicidal rumination, over the consequences of unauthorized absences. The present illness, as recorded by the psychiatrist contained no reference to combat and neither did the past history which happened to be singularly free of evidence of psychiatric abnormality. In fact, this particular patient on the service psychiatric abnormality. In fact, this particular patient on the surface at least seemed to have been exceptionally well adjusted to combat. However, the diagnostic impression was "A mild adjustment disorder with strong homoerotic and latent passive dependent factors." A routine history was obtained by our social worker from his family who volunteered the information that the patient had shown a rather personality change on his return from Korea in 1951. In addition to other manifestations he showed a marked attitude reaction, phobic responses to reminders of combat and in the past at least had shown the typical dream life.

The medical officer in charge of the case, with his attention thus transiently directed to the combat experience, asked the patient about these experiences and was rewarded by a spontaneously cathartic outpouring which resulted in some apparent symptomatic improvement. (It is interesting that none of the three patients volunteered any information about their combat experience or its apparent psychological effects on them.) Thereafter, for two months of hospitalization there was no reference to combat or its effects. No further abreactive at

tempts were made Shortly before his discharge the patient went AWOL and claimed amnesia for his absence The doctor's progress note almost, but not quite hits the mark "The patient's last recollection was of being bumped from behind by another car while driving his own The loud bang (of the collision) took me by surprise I felt very shaky and tense and I could not understand why such a little bump should excite me so much The patient feels that something in the accident was reminiscent of his past but cannot pinpoint his feelings in this regard Anyone who has seen a violent dissociative response of a combat neurotic under Amytal (brand of amobarbital) when a loud noise is deliberately made by the therapist in the hope of precipitating abreaction, may have some idea of what happened in this case

Case 2. The second patient also a sergeant was admitted to the hospital with diagnosis undetermined, hypertensive vascular disease A history taken by the Medical Department contained no reference to his 11 months in combat which included some particularly harrowing experiences Likewise an extensive neuropsychiatric consultation made no reference to these overseas experiences He was transferred to the Psychiatric Department because of suicidal feelings and "tension" A psychiatric history of the present illness and an extensive past history which incidentally also indicated a good enough pre-service adjustment contained no references to the effect of combat except that it was mentioned that he was the recipient of a Bronze Star An alleged suicidal attempt while in Korea was described this being attributed largely to family difficulties at home Furthermore a work up at a naval hospital at the time of this suicidal attempt failed to mention anything about combat The diagnostic impression was schizoid personality Nowhere in the progress notes that succeeded was there any reference to combat or its effects Psychologic tests were reported as evidencing depressive components in a passive dependent personality with little likelihood of genuine suicidal attempts A three page social service history taken by our worker some time after the patient's admission to the service revealed that "when he returned to the States in July 1951 he seemed to have many symptoms suggesting an acute anxiety state had frequent combat nightmares and would awaken sweating and anxious" This type of dream plus morbid daydreaming about his experiences with particular reference to the fact that he was one of 16 survivors of an outfit that had originally had several hundred personnel had continued with various remissions and exacerbations until the present time

Case 3 The case of a third sergeant happened to be worked up by two different medical officers because of reassignment of one of them Each doctor took a complete history In the first anamnesis there was no reference to combat The second and very extensive history described the man's combat experience but made no mention of his reaction to these experiences In one case the chief complaint

was recorded as follows "History of gradually deepening depressiveness and unworthiness in recent months in apparent relationship to an affair with a married former sweetheart, now in the process of divorce." In the other write up, the principal complaint was indicated as nervousness and "trouble in public speaking." Finally, our capable social worker this time missed the import of combat entirely and focused exclusively on current problems. This is not to suggest that the solution of current problems may not be of great importance, the fact remains that these problems had developed and been augmented because of the existence of a "traumatic" neurosis. The patient manifested a great deal of anxiety and hostility, and strenuous attempts were made by his medical officer to relieve him of these symptoms by discussion of current life difficulties, without much effect.

Finally, 6 weeks after admission, his medical officer asked me to interview the patient with a view to offering therapeutic suggestions. Basically the sergeant appeared to be suffering from the effects of a combat induced "traumatic" neurosis, characterized by marked anxiety associated with extreme autonomic overaction, extreme irritability, outbursts of rage, acoustic hypersensitivity, marked startle reaction, inability to tolerate discussion of painful experiences in Korea, and continued dreams of combat experiences.

At this point the question might be asked, "Once the conclusion has been reached that combat experiences have made a contribution to the development of a man's psychiatric illness, does this make any difference in the therapeutic management of the case?" In this case, over a period of about 6 weeks a total of 6 abreactive sessions were carried out, using Pentothal Sodium (brand of thiopental sodium). In each instance there was violent abreaction of specific combat experiences, associated with extreme terror and guilt. The patient relived these experiences in the present tense and in minute detail and with electrifying intensity. After each session, there appeared to be some improvement in symptoms. Headaches that he had complained of disappeared, anxiety became markedly reduced, outbursts of irritability entirely disappeared, dreams of combat cleared up, appetite was restored, and the patient stated, "I haven't felt as good as this for years." This man was ultimately discharged from the service and a chance follow up 6 months later revealed that he had held his improvement.

Although not germane to the purposes of this presentation, it is interesting to speculate why these abreactive sessions seem to be associated with marked improvement. Is it some form of nonspecific "shock" treatment, the simple effects of repeated violent expression of repressed emotion, the significance of the tender and solicitous laying on of hands involved in these 6 sessions, or is it the opportunity vigorously to ventilate the incubus of a long festering guilt and terror experience in the presence of a reassuring and guilt relieving authority?

dren, over aggressive children, children who swear profusely, children who set fire children who steal children who fabricate, children who are involved in disturbing sexual activity, children who persist in thumb-sucking, and children who are frankly schizophrenic. In attempting to analyze the general situation in the Far East, many factors appeared to be important in the pathogenesis of these problems.

### FAMILY RELATIONSHIP IN NEW ENVIRONMENT

We are concerned with families who have been transplanted from their home environment to one that is unfamiliar to most of them. Some of the families come to this new environment willingly, and others come reluctantly. Parents and children leave friends and relatives behind and find themselves one morning in a strange land where customs are different, where they know no one and where the process of establishing new friendships has to begin all over again.

Often children leave school in the middle of the year. After being out of school for several weeks they start in a different and unknown setting and some of them find the transition extremely difficult.

In most instances families begin their lives in this environment in private rental houses where communication with natives is difficult because of language barrier and where communication with fellow countrymen is hampered because of lack of telephones and transportation.

The father frequently precedes the rest of the family by several months and may during that time establish some kind of extramarital relationship with local women. On arrival the wife often suspects or fantasizes such relationships, in either case her security is threatened in varying degrees. Divorce may be talked about openly and sometimes it appears that the children are the only forces keeping the family intact. At times the family is able to have a full time maid and the parents take advantage of this seemingly fine state of affairs to leave most of the direction of the children to the maid. Concomitantly with this the base activities for children sometimes are utilized to excess, the children being pushed into the activities without needed parental guidance.

The nature of the father's work occasionally keeps him away from home for unnatural lengths of time and this is cause for concern in the family.

Thousands of miles separate the families from their relatives. The distance accentuates normal worry and anxiety about the health and welfare of those who mean much to them.

These factors are but a few of the multidimensional influences affecting service families in the Far East. Some of them arrive in the theater with already disturbed family relationships, and one additional factor or a combination of factors may be instrumental in precipitating still worse relationships that are reflected in the disturbed behavior of a child.

The disturbance in the family becomes cyclic—the father is unhappy, the mother is unhappy, and the child is unhappy. This turbulence often is reflected in reduced effectiveness of the father as a member of the Air Force. With the current and rightful emphasis on total family care in the Air Force, it was considered important that an attempt be made to work with these problems in such a manner as to maintain and facilitate the integrity of the family unit. Consequently, a plan was developed to establish a child guidance program by which both the child and his parents could be assisted.

### STANDARD CHILD GUIDANCE CLINIC

The usual child guidance clinic of the general type described by Scheibel, Zehrer, and Chambers<sup>1</sup> and by Montague and Thompson<sup>2</sup> is operated in a fairly definite and well established pattern. The procedures are time consuming, automatically limiting the number of children who can be seen. Professional personnel represented are clinical psychologist, psychiatric social worker, and psychiatrist. When a child is referred to such a clinic, a certain routine is followed. Initially the social worker will conduct an intake interview with the parent or parents, then the child may be seen several times by the psychologist for a battery of testing, and the physician may observe the child in the play therapy setting before all of the data collected are discussed and analyzed at an intake conference. At that time a decision is made as to who will be the child's therapist and who will work with the parents. Then a series of appointments are made, the frequency varying from once to several times a week. Following each therapy session with the child and his parents, brief discussions are held between all the professional personnel concerned with the sessions just concluded. Periodically, staff conferences are held for review of the case in its entirety.

### THE SIMPLIFIED PROGRAM

Such an approach to the treatment of emotional problems in children is ideal, but it was obvious from the first that we could not follow an ambitious program because of many limitations, chiefly in available time and personnel. It was impossible to predict very far in advance how many of the three disciplines (those of the clinical psychologist, psychiatric social worker, and psychiatrist) would be represented on the staff, and whether, when all three are represented, all would be interested in working with the problems

of children. Only a fraction of our time could be devoted to such a program because of a large outpatient service for military personnel and dependents, in addition to a 30 bed ward for the military—all of which are time and energy consuming. What could be done under the circumstances? We declared our interest in working with such problems insofar as time and personnel permitted, a play therapy room was equipped, and we were in business.

The process had to be streamlined, and this is essentially our operation at present. The social worker or social work technician interviews the parents as soon as possible after the initial referral, obtaining as much background data as possible and recording his observations of the parents and their interaction during the interview. A subsequent appointment is made for the parents and child to see the physician. At this time the child is observed in the playroom for about 30 minutes, and then the parents are interviewed briefly. On the basis of the data available the physician conducts a kind of "summing up" with the parents.

At this point one of several things may happen:

1 It may develop that the problem is not a real one and that what is needed is for someone to explain to the parents that the behavior of the child is normal for his age.

2 It may be that the problem is not severe enough to require frequent visits to the clinic. In this case, the physician points out to the parents during the "summing up" what factors are important in the particular situation and makes suggestions. The parents are sent home to carry out these suggestions for four to six weeks, after which they are to call us. Many times the problem is resolved in this length of time. If not, parents and child are brought back for another appointment, more data is gathered and again certain suggestions are made in view of whatever has transpired in the interval. They are asked to report again in four to six weeks, and if at the end of that time appreciable progress has not been made, we take them on more frequently. In this case the parents are usually seen by the social worker while the physician works with the child. Informal discussions are held among the professional personnel from time to time so that data can be exchanged and evaluated.

3 In some instances it is obvious from the initial visit of the child and his parents that the matter is serious and will require a more intensive approach. Appointments are made at weekly or more frequent intervals for the child to be seen in the playroom while the parents are being seen by the social worker.

4 In the rare situation that is considered inoperable under the circumstances, it is recommended that the family be returned to the United States where the needed assistance can be obtained.

If appropriate, we make contact with some civilian agency in the United States where the parents can seek help

### DISCUSSION

The types of problem situations referred to the clinic may be (1) behavior problems such as excess timidity, fearfulness, and seclusiveness—problems manifested generally in the personality, (2) problems manifested in socially unacceptable behavior such as fighting, bullying, temper tantrums, disobedience, exhibitionism, stealing, cruelty, and sexual difficulties, (3) problems of habit formation such as enuresis and speech defects, (4) problems of development such as mental retardation, mental acceleration, and difficulty in reading and spelling, and (5) psychosomatic problems such as urticaria and asthma

Our preliminary observations regarding the need for a child guidance program have been substantiated. There is no well defined yardstick by which to measure the success of such a program, but no one can overlook the disappearance of disturbing symptoms in a child and better integration of the family as a unit. There is considerable evidence to suggest that such a program has contributed appreciably to the morale and efficiency of the families who have used the facilities of the clinic. The program has been received enthusiastically by teachers and school nurses. Further evidence of the acceptance of such a program in the ever widening geographic area from which patients are referred.

The modified approach that we have described has worked effectively in civilian practice and is considered adaptable to the needs of the Air Force setting at this overseas hospital. Here the work must be accomplished by limited personnel operating under the handicap of a heavy patient load, which precludes, particularly in an overseas area, the operation of a child guidance clinic along classical lines.

# OBSERVATIONS ON THE DYNAMICS OF LEADERSHIP

## A Methodologic Approach

DENNIE L. BRIGGS *Lieutenant MSC, USN*  
IRVING D. BERG *Lieutenant MC USNR*

WHILE STATIONED in a large naval general hospital for the past two years we were impressed by the interaction among various staff members, between medical, surgical, and psychiatric patients, and between staff and patients. In addition to the medical staff, consisting of career and reserve medical officers, there were medical administrators, officers of the allied medical sciences nurses, and hospital corpsmen all with distinct symbols as to their rank either in military or civil service. The patients were officers and enlisted personnel, both men and women, of various ranks and rates, in addition to dependents.

We often were struck by the interaction that took place in so many different ways and on so many different levels, particularly the formation of groups within the military structure. Often, the hospital, extraordinary situations occurred that involved personnel with higher or lower professional status and that called for personal and social adjustments not encountered elsewhere in the military. Even within groups formed spontaneously, there was the factor of intertask relationships where social status was not recognized as easily, but where prescribed behavior was rigidly observed.

In the course of observations made while teaching, conducting group therapy, and holding ward staff meetings and discussion groups, we were impressed by the development within the groups of a certain hierarchy that seemed to establish itself automatically. We also were aware of what seemed to be the assumption of positions of leadership, "followership" and "going along ship" by members of the groups. We became interested in how the language, perspective, and viewpoints varied among the dif-

---

Presented at the annual meeting of the American Sociological Society, Washington D. C., 1955.

ferent groups. We thus became curious as to what went on in those "natural groups" and what factors took place in the establishment of the hierarchical arrangements within the groups, in addition to finding out more of the purposes served by these relationships.

Noting the observations made by Parsons,<sup>1</sup> Caudill and associates,<sup>2</sup> Stinton and Schwartz,<sup>3</sup> Fox,<sup>4</sup> and others concerning the participation of the hospital as a social system in the treatment and course of illness, we were interested in developing more systematic methods of observation, particularly of the groups that formed and of the dynamic interaction that occurred within those groups.

Any particular group that was not formed artificially by calling together various individuals as subjects into a nonmeaningful group became a subject for investigation. We observed the patients getting together themselves, hospital corpsmen working together, the staff of a particular ward, or coterie, thus our studies represent particles of the vastly complex interaction going on in a military hospital.

### METHODOLOGY

In this article our main interest is to present a methodologic approach that was designed to integrate sociologic, psychologic, and psychiatric theory and technique. We wished to recapture the social setting of the particular group under study with a minimum of disruption by research procedures. Each technique was chosen as one with which the members were familiar, or one that contributed to the atmosphere being investigated. The groups selected were "natural groups" in the sense that the members themselves had gotten together as friends or associates, or were working together in a staff-patient relationship. Those groups studied had close contact with the investigators in a teaching or therapeutic relationship. It was our belief that the spirit of cooperation exhibited contained little or no acquiescence. The techniques themselves were chosen and adapted to keep the setting as natural as possible within the framework of the hospital.

In considering the feasibility of adapting acceptable research procedures from the various disciplines to contribute to a holistic approach, we chose those methods that we believed were sound experimentally and acceptable to our participants. Before using any procedure with which the group was not familiar, its use was discussed and worked through in the group. For example, when tape recordings were used—a procedure familiar to most of the participants—group members operated the recording apparatus themselves and were allowed to listen to the playback at any time.

We selected the Rorschach test because it is an accepted technique in clinical psychology, was a familiar procedure at the hospital, yet presented a relatively unstructured stimulus that most of the group members had not actually seen previously, although all knew it was a device to reveal material unknown to the testee. Thus some "test anxiety" was mobilized as part of the experimental procedure. This was utilized and accounted for, as we shall discuss presently.

The Rorschach test was individually administered and was interpreted in the traditional manner as presented by Beck.<sup>4</sup> Later, a modification was introduced that had not to our knowledge been used previously. In one of the group sessions, it was announced that the next session would be devoted to an experiment. In the following session, the Rorschach cards were shown to the group as a stimulus for discussion. The members were asked what they saw as a group in each card in an allotted time, and their impressions were recorded. Immediately following this session, their individual impressions were taken again to measure any possible aftereffects of the interaction that had occurred.

The Rorschach test thus was used clinically to obtain a personality description of each member and of the group as a whole, in addition to being used thereafter as a somewhat familiar stimulus for discussion. Its unique feature in this experiment, however, was that in a sense we also obtained a measure of the "group personality" together with an estimate of both individual group dynamics in operation. We saw an individual's private self as well as those he voiced publicly and the manner in which he operated in a group. In addition, we watched similar interaction for the group as a whole. An individual might see a percept that through previous research has been established as one indicating a particular disturbance in psychic functioning, and introduce this percept into the group discussion. If the percept was ego-alien or not acceptable to the group, disagreement might ensue and the individual would be forced to make a stand or withdraw. Through later content analysis of the percepts, we were thus able to gain insight into the particular meaning of the individual's thinking both privately and in the group setting.

Group sessions were tape recorded and transcribed. The interaction was charted according to a modification of Baltes' "Interaction Process Analysis,"<sup>5</sup> momentarily disregarding interpretation of the psychological meaning of the test responses.

At another session, the groups were asked to make various choices of the members' behavior, utilizing Taguri's "Relational Analysis" technique.<sup>6</sup> Each member was seen individually for psychiatric interviews and an associative anamnesis was taken. Impressions also were noted from the content of the group meetings (i.e., reactions to lectures, feelings expressed in therapy

sessions, et cetera) by the investigators who were meeting with the groups.

### OBSERVATIONS

The observations presented here are tentative and warrant a very extremely cautious interpretation and generalization. We have not subjected them to statistical verification and have not used them outside the clinical setting of the hospital. They are based on the basis of a number of hypotheses that we are investigating.

We observed through the interaction and the Rorschach responses that there were many personal feelings and ideas present which a person would not voice publicly (i.e., his private ideas), and others that a person could not reveal even to himself, as he was not conscious of their existence. Our research thus far brings out the following points regarding the interaction of the group and the dynamics of the leader in a spontaneous social setting.

(1) In group discussions, the members were selective in the material they brought forth, and tended to reveal those private ideas and feelings least disturbing or alien to the group (i.e., they revealed most often those ideas that were more acceptable to the group or "group syntonic").

(2) Where some of the group-apparent material coincided with ego-alien material (i.e., material which was unacceptable to the ego and therefore not previously capable of being integrated by the ego) the ego-alien material became integrated into the individuals' experience and following the group experience, they could safely add these ideas to their conscious repertory.

(3) The leader, as obtained by sociometric choice, was the one who was more capable of incorporating by his ego-integrative capacity ideas that came from the group, and possibly ideas that he could not previously have brought to acceptance, i.e., those that might have been unacceptable to him before. Interestingly enough, this factor appeared to operate in groups of psychiatric patients as well as in nonpatient groups.

(4) The degree of freedom (via the group conscience) seemed to be more limited than that of the individuals composing the group. Socially unacceptable ideas that were not privately ego-alien still tended to be treated as unacceptable in the group. The group served to censor ideas and admitted those considered socially mature and thus more socially acceptable. The individual privately entertained as acceptable ideas that in a social setting were voiced as unacceptable, thus establishing and reinforcing mores and social controls.

(5) The leader subtly introduced his private ideas to the group. If they were rejected, he did not enforce them (He did not want to press the point when he noticed the tenuous status of his ideas with regard to acceptance by the group). Did the other members take on his ideas privately, while not publicly?

We selected the Rorschach test because it is an accepted technique in clinical psychology, was a familiar procedure at the hospital, yet presented a relatively unstructured stimulus that most of the group members had not actually seen previously, although all knew it was a device to reveal material unknown to the testee. Thus some "test anxiety" was mobilized as part of the experimental procedure. This was utilized and accounted for, as we shall discuss presently.

The Rorschach test was individually administered and was interpreted in the traditional manner as presented by Beck.<sup>4</sup> Later a modification was introduced that had not to our knowledge been used previously. In one of the group sessions, it was announced that the next session would be devoted to an experiment. In the following session, the Rorschach cards were shown to the group as a stimulus for discussion. The members were asked what they saw as a group in each card in an allotted time, and their impressions were recorded. Immediately following this session, their individual impressions were taken again to measure any possible aftereffects of the interaction that had occurred.

The Rorschach test thus was used clinically to obtain a personality description of each member and of the group as a whole, in addition to being used thereafter as a somewhat familiar stimulus for discussion. Its unique feature in this experiment however, was that in a sense we also obtained a measure of the "group personality" together with an estimate of both individual and group dynamics in operation. We saw an individual's private thoughts as well as those he voiced publicly and the manner in which he operated in a group. In addition, we watched similar interaction for the group as a whole. An individual might see a percept that through previous research has been established as one indicating a particular disturbance in psychic functioning, and introduce this percept into the group discussion. If the percept was ego alien or not acceptable to the group, disagreement might ensue and the individual would be forced to make a stand or withdraw. Through later content analysis of the percepts we were thus able to gain insight into the particular meaning of the individual's thinking, both privately and in the group setting.

Group sessions were tape-recorded and transcribed. The interaction was charted according to a modification of Balas' "Interaction Process Analysis,"<sup>5</sup> momentarily disregarding interpretation of the psychological meaning of the test responses.

At another session, the groups were asked to make various choices of the members' behavior utilizing Taggart's "Relational Analysis" technique.<sup>6</sup> Each member was seen individually for psychiatric interviews and an associative anamnesis was taken.<sup>7</sup> Impressions also were noted from the content of the group meetings (i.e. reactions to lectures, feelings expressed in therapy

and to their countrymen, in the case of those to whom the has entrusted its security, is far reaching.

We entered into this research with no preconceived ideas. We have made no attempt to test hypotheses. The research is in progress and specific findings must await stimulation. The next phase of our research emphasizes the invariants of ideas that are made public in a spontaneous social group, making use of sound motion pictures of social setting as much as possible.

Our intention in this article has been to present a new idea and an approach to observation on leadership. We have usually to arrive at a well-justified appraisal, involving the use of acceptable methods from sociology, dynamic psychiatry, psychology, and other behavioral sciences combined in a total approach, rather than from any specific discipline.

#### INCREASE IN DEATHS FROM CORONARY DISEASE

"Much of the rise in the recorded death rate from coronary artery disease during the past 15 years reflects merely the increasing proportion of older people in the population and changing fashions in certifying heart disease as a cause of death. The real increase has been relatively small certainly not of the magnitude to justify the alarm expressed in the press and elsewhere."

—*Statistical Bulletin*  
Metropolitan Life  
p 1 Feb 1957

(6) Those persons whose egos were more capable of integration while not of leadership caliber, did this more often (i.e. they functioned more at a private level). Are these persons capable of becoming more of a leader in another group, after absorbing something of the leader that they did not have before? We believe they are, depending on the "social climate" of the new group and the new dynamics involved.

(7) The "going-alongers" were the least affected by the responses in any group. They also were the most disturbed clinically, both socially and psychologically (less participation in community affairs, et cetera). They manifested ambivalences of their roles and ideas as contrasted to the leaders and the followers who presented active expressions of their roles. The members who went along with others only hesitatingly raised points, mainly agreed, and went along with the others.

(8) In general, group experiences seemed to reduce potentials for expression (reduce the number of private ideas that were expressed publicly) but what was individually retained was more reality oriented and thus more socially acceptable. (After group experience, ideas were less frightening to the individual. This is perhaps one of the most important processes involved in group psychotherapy.) Original ideas were not lost but were condensed or diluted.

(9) The leader was one who was more able to accept his private ideas plus the ideas of the group and to integrate these into his own thinking.

(10) Leadership imparted to the follower and to other group members an crucial and important information for integrative functions.

#### DISCUSSION

It is recognized that mere participation in any sort of experiment engenders a certain amount of apprehensiveness, as does participation in most social situations. We have attempted to minimize "test anxiety" by familiarity with the investigators and by working through the feelings of the group members who are being studied prior to the procedure being introduced.

In the group setting, the leader has to make a choice as to whether he will run the risk of revealing some of his private thoughts and endure the stress involved in facing the possibility of losing his position. If he chooses to do so, this course of action is socially meaningful and presumably gives some measure of his stability where real or imagined stress is involved. Thus a man may be an acknowledged leader by military rank, social status, or as empirically defined by Bales' or Taguiri's procedure, but under the stress of revealing his inner thoughts he may break down. In a benign setting, decisions of this type are made under no great stress such as would be involved under threat of starvation, loss of one's life, or extreme pain, yet under these and other types of stress, leaders selected by the best available means do break down. The effect on morale to their associates

and to their countrymen, in the case of those to whom it has entrusted its security, is far reaching.

We entered into this research with no preconceived ideas. We have made no attempt to test hypotheses. The research is in progress and specific findings must await stimulation. The next phase of our research emphasizes the use of ideas that are made public in the social setting, social group, making use of sound motion pictures to simulate the social setting as much as possible.

Our intention in this article has been to present a methodology and an approach to observation on leadership. We hope eventually to arrive at a well-studied appraisal, involving the use of acceptable methods drawn from sociology, dynamic psychiatry, psychology, and other behavioral sciences combined in a total approach, rather than from any specific discipline.

## CASE REPORTS

### Ovarian Abscess Complicating Pregnancy

ROBERT C. LOEHN *Captain USAF (MC)*

**O**VARIAN ABSCESS complicating pregnancy is rare and few cases are reported in the literature. In the earliest case reported, by Aitken<sup>1</sup> in 1869, the patient developed a fatal peritonitis from rupture of an ovarian abscess during premature labor. In 1891 Coe<sup>2</sup> reported three cases of acute oophoritis complicating pregnancy. One patient improved under treatment, the second patient had an ovarian abscess rupture into the urinary bladder and later delivered a viable infant, the third patient had a septic episode in her seventh month of pregnancy, had an uneventful term delivery, and during her postpartum course had a surgical exploration because of an ovarian abscess. Brindeau<sup>3</sup> in 1917 reported a case of a fatal peritonitis that developed from rupture of an ovarian abscess immediately after a term delivery.

Pomini<sup>4</sup> described a case of a ruptured ovarian abscess which developed on the fifth day following a rapid, uneventful delivery, the outcome was fatal. An interesting and confusing case was reported by Dolan<sup>5</sup> of a left ovarian abscess associated with a right tubal pregnancy. Curmin<sup>6</sup> recorded a case of an ovarian abscess discovered in the fourth month of a patient's pregnancy. Exploratory laparotomy revealed free pus in the peritoneal cavity from a right ovarian abscess, and a right salpingo-oophorectomy was performed. The patient aborted a congenitally malformed infant twelve hours after surgery.

In a comprehensive discussion of ovarian abscess, Black<sup>7</sup> revealed that in 105 cases reviewed, the causative organism in 95 per cent of the cases was streptococcus. The other causative organisms were staphylococcus, colon bacillus, tuberculous, gonococcus, pneumococcus, et cetera. Ovarian infection occurred by the hematogenous route or by contiguity. It was Black's impression that primary involvement of the corpus luteum is not necessarily involved in all ovarian abscesses.

The following case is presented because of its rarity.

---

From Fitzsimons Army Hospital Denver, Colo. Dr. Kaehn is now assigned to 405th U. S. Air Force Hospital APO 237 New York, N. Y.

## CASE REPORT

**History** A 37 year old white female, para iii, gravida iv, was admitted to this hospital on 30 July 1956, with a history of having had mild lower abdominal cramping and pelvic pain for approximately 9½ hours Her last menstrual period was on 11 February 1956 The patient had been followed in the Prenatal Clinic at Fitzsimons Army Hospital since 14 May 1956 Examination at her initial prenatal visit revealed a uterus enlarged to the size of a 3 months pregnancy and a cyst, 2 cm by 2 cm in size, of a Skene's gland At that time the history obtained indicated she had had a pelvic inflammatory disease several years prior to her present pregnancy On admission to the hospital, there was no history of bleeding or rupture of the membranes, on closer questioning of the patient, it was found that she had had a similar episode of pain in the lower abdomen, especially in the right lower quadrant, in May 1956 and again in June 1956 At the June visit, a pelvic examination was not performed For 2 weeks prior to admission the patient had noted some irregularity of her heart, however, she had not experienced other cardiovascular symptoms

**Physical Examination.** Physical examination on admission revealed the following positive findings Blood pressure, 115/60 mm Hg pulse rate, irregular fine, moist rales heard posteriorly over both lower lung fields on auscultation of the chest, the fundus of the uterus was at the level of the umbilicus, there was marked tenderness in the right lower quadrant of the abdomen extending into the right flank area and mild generalized tenderness over the entire abdomen, marked right costovertebral angle tenderness Pelvic examination was deferred because the examiner thought that the patient might be in immature labor

**Laboratory Studies.** Hemoglobin was 12 grams per 100 ml, hematocrit, 36 ml per 100 ml, urinalysis, 6 to 8 white cells per high-powered field with multiple clumping of the cells in the urine Numerous bacteria were seen in the catheterized specimen of urine

**Course in Hospital** On 31 July 1956, the patient complained of anorexia and mild nausea and vomiting on several occasions Examination of the abdomen revealed mild distention and a decrease in the quality of bowel sounds It was considered that the patient had an acute pyelitis and a paralytic ileus On the same date a chest roentgenogram was obtained which was interpreted as within normal limits A cardiac consultation was obtained, and the cardiac service believed that no heart disease was present The electrocardiogram was interpreted as showing frequent premature ventricular contractions A flat plate of the abdomen obtained on the same day revealed a mild ileus, and a soft tissue shadow was observed in the lower abdomen displacing the uterus upward, probably representing an extrauterine mass in the pelvic region

The patient was treated conservatively for paralytic ileus and she responded very well. On 3 August 1956 a pelvic examination revealed a large mass posterior and inferior to the uterus the size was estimated to be approximately 12 cm in its greatest diameter. The mass was moderately tender. Up to this time the patient had been relatively afebrile. The patient had been on penicillin and streptomycin sulfate since 31 July, when the diagnosis of pyelitis had been made.

On 6 August 1956 the patient was taken to surgery where, under general anesthesia exploratory laparotomy was performed. At the time of exploration it was found that the large mass was on the right posterolateral surface of the uterus and was a large ovarian abscess. The fallopian tube on that side was moderately hyperemic however it was not adherent to the surface of the abscess. The ovarian abscess was adherent to the right posterolateral surface of the uterus, to the posterior wall of the right broad ligament and to the right lateral pelvic wall. Blunt dissection was employed in an attempt to remove the abscess and during this procedure the abscess was inadvertently ruptured. The entire right ovary with the abscess was removed. Culture of the contents of the abscess revealed alpha hemolytic streptococcus. The abdomen was closed in layers. The patient tolerated the procedure well with minimal blood loss.

Both preoperatively and postoperatively the patient was given procaine penicillin G (600 000 units) twice daily, and also 0.5 gram of streptomycin sulfate twice daily. Postoperatively the patient did very well and had a relatively afebrile course.

It might be noted here that the patient was placed on 50 mg of progesterone daily beginning the day before surgery and continued on it to 10 August 1956. On the 5th and 6th postoperative days the skin clips were removed. Pelvic examination prior to patient's discharge from the hospital on the 8th postoperative day revealed some thickening of the adnexal area more on the right side, but it was nontender.

**Postoperative.** The patient was placed in the obstetrics clinic and followed there for the remainder of her prenatal care.

The patient was admitted to the obstetrical labor room on 18 November 1956 in active labor. Labor progressed satisfactorily under analgesia induced by Demerol Hydrochloride (brand of meperidine hydrochloride), scopolamine and Thorazine Hydrochloride (brand of chlorpromazine hydrochloride). After five hours and five minutes the patient was delivered spontaneously under pudendal block anesthesia of a viable male infant. There were no complications in the third stage. The postpartum course in the hospital was uneventful.

**Pathologic Findings.** The ovarian abscess (fig. 1) was an irregular cystic mass weighing 150 grams. The external surface was smooth and glistening with marked congestion. The free surface was gray in color the attached surface was deep red. The contents consisted of a homogenous purulent material having a greenish cast with no

Figure 1 Gross specimen of ovarian abscess showing glistening congested surface. Darkened area represents area attached to the surrounding structures.

odor. The walls of the abscess averaged 3.0 to 4.0 mm in thickness. Microscopically, (figs. 2, 3) the walls were very edematous and heavily infiltrated by acute inflammatory cells. There was localized proliferation of the external mesothelial cells. An acute fibrinous exudate covered the external surface. Inflammatory exudate lined the abscess cavity.

#### SUMMARY AND CONCLUSIONS

A case is presented of a patient's ovarian abscess complicating pregnancy. Reports of such cases in the literature are rare. The patient was admitted to Fitzsimons Army Hospital on 30 July 1956, with a history of having experienced mild lower abdominal cramping and pelvic pain for approximately 9½ hours. She had been followed in the prenatal clinic at this hospital since 14 May 1956. On 3 August 1956, a pelvic examination revealed a large mass posterior and inferior to the uterus. The afebrile course of the patient added to the confusion in considering the preoperative differential diagnosis of a pelvic mass complicating pregnancy.

Due to the size and to the unknown nature of the tumor, surgical intervention was deemed necessary. The duration of ges-

Figure 2 Microscopic view of a section of the wall of the ovarian abscess.  
( $\times 75$ )

Figure 3. Higher-power view of a section of the wall of the ovarian abscess.  
( $\times 275$ )

tation was ideal for considering an operative procedure. With the use of penicillin and streptomycin sulfate during the preoperative and postoperative periods, a severe peritonitis was avoided even though accidental spillage of the contents of the abscess occurred at surgery. Whether parenteral progesterone was of value in the continuation of the pregnancy is debatable.

It was considered that the streptococcus organism was carried to the ovary by the hematogenous route but the actual date of the primary involvement of the ovary is not certain, and may have been in May 1956 when she had experienced pain in the right lower quadrant of the abdomen. By removing the abscess the future danger of its rupture was avoided. Rupture of the abscess could have occurred at any time during pregnancy, during labor, or during the postpartum course, and could have been fatal.

#### WHO FIGHTS DISEASE GLOBALLY

The yearly investment by the United States in WHO of about one cent per \$1 000 of national income, or less than the cost of a three cent postage stamp per capita, is small indeed when measured against the huge returns of increased productive labor, higher standards of living and world amity. WHO in its global fight against disease, is doing its share to bring this about in an unobtrusive but highly practical way. Such constructive programs of technical assistance and training designed to win the trust of the peoples of the free world can effectively supplement the armed might of military machines as guarantees of world peace.

# Bilateral Bell's Palsy Complicating Infectious Mononucleosis

HALL G. CANTER *Captain, MC USA*  
WILLIAM R. SCHILLHAMER *Major MC, USA*

**N**OT INFREQUENTLY neurologic complications occur during the course of infectious mononucleosis. The following case of bilateral Bell's palsy complicating this disease is believed worthy of reporting as another illustration of this growing group of phenomena.

## CASE REPORT

A 24 year-old white man was admitted to this hospital on 27 August 1956 because of progressive fatigue of two weeks duration. The family history revealed that when the patient was an infant his father had committed suicide. For many years he had had recurrent mild, frontal headaches.

Two weeks prior to admission the patient noted the onset of progressive fatigue. Eight days before entry to the hospital he had chills and was feverish. The day before admission he was unable to carry out his duties of clerk-typist because of fatigue. On 27 August he noticed some swelling of the glands in the anterior part of his neck reported to the hospital and was admitted.

Physical examination revealed a well-developed and well-nourished white man who was in no acute distress. His temperature was 99.6°F, pulse rate 88 per minute and blood pressure 116/70 mm Hg. His tonsils were moderately enlarged and there was a small amount of exudate. Slightly enlarged tender lymph nodes could be felt in the anterior and posterior cervical, axillary and inguinal areas and the epitrochlear nodes also were enlarged. The spleen and liver were not palpated. The remainder of the physical examination was within normal limits.

Urinalysis and a serologic test for syphilis were negative. A roentgenogram of the chest was normal. The initial white blood cell count was 12,550 per  $\mu$ l with a differential of 27 per cent neutrophils, 66 per cent lymphocytes, 27 per cent of which were atypical, 6 per cent monocytes and 1 per cent eosinophils. The initial heterophil agglutination titer was 1:448. As noted in table 1, blood cell counts during the pa-

**N**OT INFREQUENTLY neurologic complications occur during the course of infectious mononucleosis. The following case of bilateral Bell's palsy complicating this disease is believed worthy of reporting as another illustration of this growing group of phenomena.

## CASE REPORT

A 24-year-old white man was admitted to this hospital on 27 August 1956 because of progressive fatigue of two weeks' duration. The family history revealed that when the patient was an infant his father had committed suicide. For many years he had had recurrent mild, frontal headaches.

Two weeks prior to admission the patient noted the onset of progressive fatigue. Eight days before entry to the hospital he had chills and was feverish. The day before admission he was unable to carry out his duties of clerk typist because of fatigue. On 27 August he noticed some swelling of the glands in the anterior part of his neck reported to the hospital and was admitted.

Physical examination revealed a well developed and well nourished white man who was in no acute distress. His temperature was 99.6°F, pulse rate 88 per minute and blood pressure 116/70 mm Hg. His tonsils were moderately enlarged and there was a small amount of exudate. Slightly enlarged tender lymph nodes could be felt in the anterior and posterior cervical, axillary and inguinal areas and the epitonsillar nodes also were enlarged. The spleen and liver were not palpated. The remainder of the physical examination was within normal limits.

Urinalysis and a serologic test for syphilis were negative. A roentgenogram of the chest was normal. The initial white blood cell count was 12,550 per  $\mu$ l with a differential of 27 per cent neutrophils, 66 per cent lymphocytes, 27 per cent of which were atypical, 6 per cent monocytes and 1 per cent eosinophils. The initial heterophil agglutination titer was 1:448. As noted in table I, blood cell counts during the pa-

TABLE 1 Hematologic and serologic findings in patient with bilateral Bell's palsy complicating infectious mononucleosis

Date	Total white blood cells (per $\mu$ l)	Differential count (per cent)				Hemo- globin (grams per 100 ml)	Heterophil agglutination titer		
		Neu- rophils	Lympho- cytes	Atypical lympho- cytes	Monoc- ytes	Eosino- phils	without absorption	After guinea pig kidney absorption	After beef cell absorption
8-28-56	12 550	27	66	27	6	1	115		
8-29-56	12 500	42	54	15	3	1	120	1 148	neg
9-4-56	12 650	41	59	26	0	0	120	1 224	neg
9-7-56	5 250	55	40	6	3	2	160	1 112	
10-3-56	4 850	46	50	0	2	2	135	neg	
11-15-56	7 850	45	48	0	4	3	130	neg	

patient's hospitalization gradually returned toward normal. The heterophil agglutination remained positive although the titer decreased. The hemoglobin was 11.5 grams per 100 ml on admission and gradually rose to 16.0 grams. Liver function tests revealed an icteric index of 12.8 and the cephalin cholesterol flocculation test was 3 plus in 48 hours.

The patient was placed at bed rest and given 0.6 gram of acetyl salicylic acid every four hours as needed for headaches. On the day of admission he complained of frontal headache and during the next two to three days mentioned numerous symptoms including tightness of the facial skin and paresthesias of the legs and hands. He also expressed concern over the possibility that he might have a brain tumor or other serious or perhaps fatal disease.

The ear, nose, and throat consultant found no evidence of sinusitis. On 29 August a psychiatric consultant expressed the opinion that the patient had hypochondriasis and reassurance was given. Neurologic examination at this time was normal. On 30 August the patient developed bilateral seventh nerve palsy (figs. 1 and 2). The neurologic consultant considered at this time that the Bell's palsy was due to intracranial inflammatory process secondary to infectious mononucleosis. He believed that the prognosis for recovery was excellent.

The patient continued to express hypochondriac complaints with numerous somatic symptoms and attempted to direct his own therapy. On 1 and 2 September he was given 60 units of corticotropin and on 3 and 4 September 40 units. There was no change in his clinical course with this therapy. He was given 50 mg of thiamine hydrochloride twice daily and 30  $\mu$ g of vitamin B<sub>12</sub> daily both subcutaneously. There was little change until 18 September when slight motion of the perioral muscles on the right was seen.

The patient was discharged to duty on 28 September and was followed as an outpatient. He was readmitted to the hospital on 2 October complaining of fatigue. No further abnormalities were noted and he was discharged on 6 October. A heterophil antibody test at this time revealed no titer. Over the next three or four months there was nearly complete return of function of the facial muscles. He was seen on innumerable occasions for many complaints, none of which were associated with objective findings.

## DISCUSSION

Bilateral Bell's palsy from any cause is a relatively rare phenomenon and as a complication of infectious mononucleosis is extremely rare. From a review of the literature we are able to find only two documented cases of bilateral Bell's palsy complicating this disease.<sup>3</sup>

In a recent extensive review of the complications of infectious mononucleosis by Smith<sup>4</sup> and a review by Bernstein and Wolff<sup>4</sup>

*Figure 1 The patient attempting to close his eyes*

emphasis was placed on the neurologic complications of the disease. The conclusion of those reviews is that the symptomatology and clinical findings of these neurologic complications are dictated by the site of maximal involvement, whether in the central or the peripheral nervous system. Bernstein and Wolff further stated that neurologic complications may be expected in less than 1 per cent of all cases of infectious mononucleosis. Landes, Roich, and Perlow<sup>3</sup> stated that the patient may first be seen with only neurologic abnormalities and the early diagnosis of infectious mononucleosis overlooked unless a heterophil agglutination is accomplished.

The case presented is illustrative of Bell's palsy complicating the course of infectious mononucleosis. We believe that nodes within the facial canal became involved in the inflammatory process of infectious mononucleosis and, because of the

Figure 2 The patient attempting to show his teeth and raise his eyebrows

resultant pressure in a closed space, caused bilateral seventh nerve paralysis. It is interesting that both seventh nerves were affected simultaneously. The patient was given a short course of corticotropin and thiamine hydrochloride and vitamin B<sub>12</sub> parenterally without apparent change in his clinical course. Recovery has been essentially complete.

#### SUMMARY

A case of bilateral Bell's palsy complicating the course of infectious mononucleosis in a young white male is recorded. Recovery in this case was uncomplicated. The course of the disease was apparently unaffected by steroid and vitamin therapy.

### CARE IN TERMINAL ILLNESS

Prolongation of life, merely for the sake of a brief postponement of death, does not appeal to me. Sometimes it is difficult to know when further treatment becomes useless. On the other hand, there are many times when we do know and can predict the outcome if either of two alternative courses is selected. Typical of this situation is ureteral obstruction in terminal carcinoma of the cervix. Uremia is a common cause of death with cervical carcinoma. Moreover, it represents a gradual fading and dimming of consciousness, and to me would seem to be an easy and painless way to die. Nevertheless, there are those who would perform cutaneous ureterostomy or pyelostomy on such patients. This might prolong life by six months and certainly would restore the patient to consciousness and awareness of her surroundings. But, what does she pay for these six months? At least the terminal two or three weeks will be associated with great pain and any or all of the disagreeable symptoms of late cervical cancer. I would not wish this for a loved one if the alternative were a relatively easy and painless death hastened perhaps a few months.

On the facade of the Union Station in Washington, D. C. is carved in granite, the admonition, "Speed the parting guest." I do not quote this as a plea for euthanasia. It is a plea to the physician to refrain from unnecessary heroics. When confronted with a rational and sentient patient, about to embark upon the final phase of his terminal illness, the physician should ask himself the question, "If I were the patient, what would I want done to me?"

# Ganglioneuroma

RICHARD C SCHULTZ, *Captain MC USA*  
PHILIP J NOEL, Jr. *Colonel MC USA*

**G**ANGLIONEUROMA was first described by Loretz<sup>1</sup> in 1870 in a thoracic sympathetic chain however, according to Fung<sup>2</sup> the entity was prophesied by Virchow about 1865. The tumor is defined as a rare, benign tumor composed of differentiated sympathetic ganglion cells mixed with great numbers of nerve fibers sheathed by Schwann cells. Although the tumor is considered benign a ganglioneuroma with metastasis to lymph nodes was described by Miller<sup>3</sup> in 1908 and corroborated by Beneke<sup>4</sup> and Berner.<sup>5</sup> Neuroblastoma is the malignant counterpart of the tumor. The tumor is most common in young adults, with a slight preponderance in women.<sup>6</sup> Generally the common sites of origin are one third in the adrenal medulla one third in the abdominal and pelvic sympathetic chains, and one third from the cervical sympathetic chains and scattered in other sympathetic chains.<sup>7</sup> Willis<sup>8</sup> believed that the ganglioneuroma originates in the fetal or early postnatal period as a neuroblastoma and then matures into a ganglioneuroma. He also believed that there is always a malignant potential to this tumor.

## CASE REPORT

A 20-year old white soldier presented himself at a dispensary with complaints of constipation and weight loss since induction into the Army 4 months previously. The amount of weight loss had been approximately 12 to 15 pound. He had been conscious of a mass in the right lower abdominal quadrant which had not been tender or painful for several weeks prior to seeking medical attention. He denied the passage of any blood in his bowel movements or tarry stools. There had been no change in the size of his stools or in his bowel habits. He had not experienced anorexia, malaise, chills, fever or night sweats. Upon questioning the patient admitted that he had been aware of bilateral swelling in the supraclavicular fossae for 6 or 7 years. He denied any local or radiating pain into his arms. There was no dysfunction of the upper extremities nor were there symptoms referable to the head or neck. He denied paresthesia and muscular weakness of his extremities.

---

From U. S. Army Hospital 1 Fort Carson, Colo.

**Past History** The past history was essentially negative. The patient was a student, prior to being inducted into the service from Kansas City, Mo., on 28 February 1956. His first duty assignment was at Fort Carson, Colo., where he arrived on 8 March 1956. His mother, father, and sister are living and well. Family history of cancer was negative. The patient had the usual childhood illnesses and knows of no serious illnesses in adult life. There had been no operations and no injuries that he could recall.

The system review was entirely negative except for the musculoskeletal system. Here, the patient admitted to having had a mild, low back pain for approximately three years without apparent cause. His pain was without radiation and seemed to be unrelated to activity. He denies any muscular weakness.

**Physical Examination** This tall, slender, young adult white man was in no acute or chronic distress and appeared well oriented and alert. His admission weight was 154 pounds, height, 6 feet 1 inch, temperature, 98.6°F, pulse rate, 80/min, and blood pressure 110/70 mm Hg. There were firm swellings in both supraclavicular fossae which had the appearance of being hypertrophied trapezius muscles. There was no tenderness in the area. There was a full range of cervical spine motion. The eyes were normal. The fields of vision were normal, and fundoscopic examination was negative. Ears, nose, throat, and mouth were negative. The chest was normal. Lungs were clear to percussion and auscultation. Heart borders were within normal limits. There was a regular sinus rhythm and no murmurs were heard. There was a slightly tender, round, partially movable mass of approximately 4 cm by 4 cm in the right lower quadrant in the cecal area. There were no palpable hernias. The genitalia were normal. Adult male with testes descended bilaterally, and digital examination of the rectum revealed normal sphincter tone. There was no mass within the rectum, but the examining finger could palpate a firm, nodular mass that seemed outside the rectum, but was pressing firmly against it. No hemorrhoids were visible. The prostate was normal to palpation and there was no tenderness. Examination of the back revealed normal spine, and a full range of motion was performed without pain. There was no tenderness to palpation of the spinous processes, and the long muscles were not in spasm. Examination of the extremities revealed a full range of motion with normal muscular strength. Neurologic examination was essentially negative, reflexes were grossly normal and no pathological reflexes were elicited. There were no palpable lymph nodes. Initial clinical impressions were that there might be either a carcinoma of the cecum or an appendiceal abscess.

**Laboratory Studies** Hemoglobin was 16.4 grams per 100 ml, leukocyte count was 8,500/ $\mu$ l, with 56 per cent segmented neutrophils, 36 per cent lymphocytes, 4 per cent band forms, and 4 per cent eosinophils. The admission urinalysis was negative. Qualitative cardiolipin microflocculation test was negative.

On admission chest and upper gastrointestinal roentgenograms were within normal limits. The small bowel studies showed elevation of the ileum in the right lower quadrant by an extrinsic mass (fig 1). Barium enema demonstrated slight elevation of the cecum and displacement of the rectum to the left by a rounded extrinsic mass (fig 2). Excretory urography showed lateral and anterior displacement of the right ureter just above the brim of the bony pelvis. Distal to this the right ureter was not visualized. The right side of the bladder did not fill because of extrinsic pressure from the right and posteriorly (fig 1). The impression was gained from this study that there was a right-sided mass arising from deep within the pelvis and extrinsic to the gastrointestinal and genitourinary tracts. The displacement of the bladder precluded retrograde urography. There was no roentgenographic evidence of bony involvement of the pelvis or sacrum. There was no calcification in the mass. Retroperitoneal sarcoma or sarcoma arising from the prostate were then considered in the differential diagnosis.

Roentgenograms of the cervical and supraclavicular soft tissue revealed bilateral soft tissue masses in the base of the neck. No cal

*Figure 1 Small bowel study showing superior displacement of the intestines. By excretory urography the bladder is demonstrated as filling on the left side only.*

Figure 2 Barium enema showing the displacement of the rectum to the left by an extrinsic mass

ifications were seen in these masses. The cervical spine films revealed gross enlargement of all neural foramina bilaterally, more marked on the left (fig. 3). It was noted that these neural foramina were rimmed by a thin line of sclerosis which would indicate that the dilatation had been a long, slowly developing process. The vertebral bodies appeared to be intact otherwise. The bony bridges between the neural foramina were markedly thin, especially on the left side. A slight increase in the cervical curvature was noted in the lateral view. Survey films of the thoracic and lumbosacral spine revealed a slight enlargement of the neural foramina to T2 and T5. Repeat chest films during the hospital course were consistently negative.

**Course in Hospital.** At the time of admission a proctoscopy was performed which was essentially negative except for a pronounced displacement of the rectum to the left by an extraneous mass. On the ninth hospital day a laparotomy was performed, and a large retroperitoneal mass presented itself in the lower right portion of the pelvis. The liver was grossly normal as were the spleen and stomach. The entire small and large bowel were examined and appeared to be normal. There were palpable shot like nodes in the root of the mesentery of

Figure 3 (A and B) Oblique views of the cervical foramina showing marked enlargement bilaterally

the small bowel along the aorta. While the mass appeared to be adherent to the urinary bladder it did not extend into it and separated relatively easily. A frozen section was made from the mass and although the pathologist could not identify the tumor he thought it might be a myxoma. He stated that it did not appear malignant but that he could not describe it positively as benign. He stated that it did not appear to be an epithelial tumor or a lymphoma.

A separate similar mass was located near the bifurcation of the aorta and the mass seemed to encircle the proximal portion of the rectum.

It was decided clinically that the tumor was of a benign nature and was spreading by local enlargement rather than infiltration and that as much of the tumor mass as possible should be resected. The greater portion of the tumor which presented in the pelvis on the right side was dissected from the urinary bladder and removed in one piece (fig 4). Other discrete tumor nodules were dissected from the pelvic wall at the bifurcation of the aorta, the hollow of the sacrum where they pressed on the rectum and from the base of the urinary bladder (fig 5). It was impossible to remove all the tumor tissue without mutilation of functioning structures. An abdominal perineal procedure was considered but was dismissed due to the probable benign nature of the lesion. Penrose drains were placed retroperitoneally and also between the rectum and coccyx and extending up into the hollow of the sacrum. Stay sutures were used in closure of the abdominal wall.

The final histologic diagnosis from regular prepared slides was that of a well differentiated ganglioneuroma without neuroblastomatous elements (figs 6 and 7).

Figure 4. View of the partially encapsulated lobular mass from pelvic region  
note multiple surface projections. Tumor has been cut to show appearance  
inside of capsule

Postoperatively, the patient recovered well, and there was very little drainage. The patient, however, had no anal sphincter control, and the urinary bladder remained on Foley catheter drainage as he was unable to void. All sutures were removed on the twelfth postoperative day. Periodically throughout the postoperative course, the bladder was filled with sterile saline to the point of discomfort, but the patient remained unable to void. On the thirty seventh postoperative day the patient voided spontaneously but incompletely. A urinary residual

*Figure 3 These specimens represent some of the rather discrete nodular partly encapsulated tumor masses dissected from around the bifurcation of the aorta, rectum and base of urinary bladder*

and cystitis were treated with antibiotics and Urecholine Chloride (brand of bethanechol chloride) and finally with continuous catheter drainage.

After satisfactory recovery from the laparotomy including recovery of anal sphincter tone and ability to have controlled bowel movements attention was turned to investigation of the supraclavicular masses. Previously taken roentgenograms revealed soft tissue densities in both supraclavicular areas and oblique views of the cervical vertebrae revealed markedly enlarged neural foramina bilaterally (fig. 3) with notable increase in cervical lordosis. On the fifty-fourth postoperative day a biopsy specimen was taken under local anesthesia from an enlarged nerve trunk of the right brachial plexus. At the time of biopsy the patient experienced a numb sensation to the right thumb. The pathologic diagnosis from this biopsy was reported as normal nerve tissue of the brachial plexus and normal supraclavicular fat pad on the right. The site of biopsy healed without complications.

Follow up cystometrograms revealed weak detrusor power of the urinary bladder the primary dysfunction being in the voiding pressure probably due to partial bladder denervation. Continuous catheter drainage was maintained. While on antibiotic therapy for urinary residual and cystitis the patient developed a bilateral axillary hidradenitis which did not respond to changes of antibiotics or soaks. Repeated cultures of these pustules produced no growth. Prior to the meeting of the Medical Board for medical discharge from the Army the patient

Figure 6 Representative area shows adult sympathetic ganglion cells in a neurofibromatous stroma. ( $\times 80$ )

had regained a considerable amount of weight and was asymptomatic except for his lack of ability to empty completely his urinary bladder. The bilateral hidradenitis subsided to some degree. The gastrointestinal system was functioning adequately, and all wounds were healed.

The patient was transferred to a named Army General Hospital from which he was discharged to inpatient care at a Veterans' Hospital near his home.

#### COMMENTS

In January 1956, Scovillo, Poleyn, and Dunsmore<sup>4</sup> described intraspinal ganglionouroma as extremely rare, dumbbell in shape, with connections extending through the intravertebral foramina. In differentiating between the paraspinal and intraspinal origins of ganglioneuroma, they pointed out that when the origin is paraspinal, the invasion into the spine is generally through only one

*Figure 7 Photomicrograph of characteristic area composed of many Schwann cells and several fully differentiated ganglion cells sheathed by satellites ( $\times 150$ ) (Courtesy of Armed Forces Institute of Pathology)*

or two foramina if intraspinal in origin, extension outward is usually through multiple foramina. There were no specific symptoms in the differentiation of these two origins. Powlands and Baird<sup>9</sup> pointed out that mediastinal ganglioneuroma may have a cervical extension presenting as a swelling above the clavicle or sternum.

In our case it was decided that the tumor probably had two separate origins: origin from the pelvic sympathetic plexus, and based on roentgenographic evidence alone, a cervical intraspinal origin.

### CONCLUSION

A case of ganglioneuroma with two probable sites of origin in a young recruit has been presented. The surgical treatment and disposition of this patient have been outlined and several points of interest from the medical literature related to this particular case have been given. It should be pointed out that roentgen ray therapy plays no part in the treatment of this tumor.

# Relation of Military Assignment to Choice of Conversion Symptoms

JEAN LYLE *Captain MSC USAR*  
JOSEPH BERCHMANS RIOUX *Captain MC AUS*

**C**ONVERSION hysteria is an intriguing nosologic entity in which there is a transfer of an unconscious conflict from the psyche to the soma. This process of materialization not only diminishes the intensity of the conflict but at times makes it evident that the conflict could be touched while in the body. Those who are afflicted appear to be more than normally impressed by physical disease in themselves and in others. In facing adversity they would modify their own bodies instead of external reality by presenting striking imitations of organic illnesses.

This article deals exclusively with one aspect of the phenomenon namely the choice of physical symptoms, and attempts to answer one question. Why, of all the organs available in the organism, is one chosen in preference to another for the reception and expression of an unconscious conflict? A typical case history as exemplified in a given military assignment is reported as an illustration.

In the literature explanations for the choice of physical symptoms in conversion have been given the generic term of somatic compliance. As far as can be estimated the body complies somatically to the reception of a conflict in one of the following ways. First by reason of congenital defect, accident or disease a part of the body may become an easy receptor of conflicts. According to Ferenczi<sup>1</sup> the function impaired by conversion hysteria is likely to be the one least important to the patient. Second, the opposite can be true. A part of human anatomy may fall prey to conversion when its maximum physiologic activity coincides with the emergence of an unconscious conflict. Thus, foot soldiers who have to make the greatest use of their legs may, under stress of combat, become paralyzed and unable to walk. Janet<sup>2</sup> believed that the function impaired by conversion hysteria is the most important one to the person. Finally, psychoanalysts emphasize the symbolism of certain organic functions which favors the acceptance of unconscious conflicts. It is known that

the mouth more adequately expresses dependence needs, while activity of the bowels better conveys the idea of hostility. "Con vex" organs according to Fenechel,<sup>3</sup> symbolically represent the male organ and male aspirations. As a consequence it could be said that, in the male, paralysis of the hand signifies the degradation of his manhood.

Ferenczi's theory is in closer connection with the case we report. Noting the prevalence of left sided hysterical paralysis among right handed people, Ferenczi concluded it was due to the fact that the left side was already partially disengaged from the patients' conscious activities and consequently "more accessible to unconscious impulses." According to other authors, the left side would be preferred by the process of conversion because it symbolically means *wrong* when the right means *correct*.

Without contesting the validity of the above views, an additional explanation is offered for the choice of physical symptoms in conversion hysteria. It is tentatively formulated as follows. All other conditions satisfied, a bodily function could become hampered by the process of conversion because of its very importance to the fulfillment of a given duty, while being at the same time the least important to the performance of an individual as an individual. For instance, it has been observed that combat sergeants and lieutenants who have to issue verbal commands develop hysterical aphonia in preference to other forms of hysteria. With infantrymen, the preference is for paralysis of legs, or for lower back syndrome, otherwise known as *camp locomotion*.<sup>4</sup> Airplane pilots for whom vision is essential more readily become the victims of hysterical blindness. Among civilians, occupational neuroses, like writer's cramp and miner's nystagmus, are other examples of the same condition.

Although removed from their area of conflict by the development of conversion, these individuals usually are returned to a modified form of duty or occupation after recovery. Such persons seem to suffer enough mental anguish to become incapacitated in one but not all forms of occupation. In other words, their ability to assume a less important job after recovery tends to prove that their suffering with conversion in the original job setup was minimal and not pronounced enough to bar recovery, in contrast to their maximal incapacity of performance.

The ocular manifestations of hysteria in relation to flying were studied extensively by Ironside and Batchelor.<sup>5</sup> They reported that these disabilities as well as their accompanying complaints were in terms of performance of duty. For example, patients often complained that they were no longer able to judge distances when flying in formation or when landing. This manner of complaining is characteristic of hysteria. Rather than expressing pain or

suffering the patients themselves ordinarily expound their inability to do a job. Indeed the idea of the job appears to be paramount in their preoccupations. In the present case, in view of the patient's assignment as a military policeman, it is believed that the paralysis of the right hand was an appropriate somatic compliance for the physical expression of a psychic conflict.

### CASE REPORT

A 29-year old left handed sergeant assigned to the Military Police was admitted to this hospital on 2 October 1956 because of inability to extend his right hand. Due to this disability his commanding officer had found him unfit for duty.

This soldier had many reasons to want to stay in the Army. He had had considerable experience in the military. From 1945 to 1948 he had served satisfactorily as an infantryman and had been discharged a corporal. In 1953 he joined the National Guard and was soon promoted to the rank of sergeant. Recent layoffs in his seasonal work as a laborer had prompted him to consider the attractions of active duty. For this father of five children these attractions were in terms of financial security and opportunity for advancement.

In rejoining the Army his plans were for returning to the Infantry and the familiarity of its routine where because of his past experience he could more easily retain his rank of sergeant. After a few weeks in a refresher course at a basic training center he gained confidence by again performing in the Army and looked forward to a permanent Infantry assignment. Instead he was assigned to the Military Police.

This came as a great shock and disappointment. He felt inadequate as a military policeman and became concerned about the preservation of his rank. He complained to the assignment section in the following terms: "I cannot see myself with a military police assignment. I know nothing about it. I want to be in the Infantry where I know my work and can teach classes." He was ordered to report to his duty station after a short leave.

The day prior to returning to duty he awakened with a paralysis of his right hand and went to a military dispensary for treatment. He reported and saluted the medical officer who noted that on saluting the patient let his right hand fall amiss without any control. The hysterical nature of this condition was easily established by the absence of organic findings and the patient was ordered back to duty. Two days after his arrival at his station he saluted his commanding officer with an awkward gesture and was ordered to the hospital with a suggestion of an assignment other than the Military Police.

The past history of this patient revealed that as far back as he could remember he had been inadequate and insecure. He quit school for fear of failure in spite of his teacher's expectation that he would attend college. His choice of work was for menial labor which was

inferior to his natural endowments, but assured him of fruitless performance

Upon admission to the hospital, the patient emphasized his inability to do duty because of paralysis of his right hand. He complained "I cannot salute and I cannot handle a gun with this hand. It has to be treated!" In the general plan of treatment, however, his hand was practically ignored. Physical therapy was prescribed, but as a device for the patient to save face in front of his fellow patients. Psychotherapy also was necessary.

It was considered that external manipulation by returning this military policeman to the Infantry would restore his normal state of health. After official confirmation of his resignation by the military authorities, the patient's improvement became obvious. He announced that he could extend his hand again. His treatment was completed with further psychotherapy, and after two and a half months of total hospitalization he returned to duty confident of his ability to carry on in the Army as a combat infantry sergeant.

### DISCUSSION

We have mentioned that a paralysis of this patient's right hand was an appropriate somatic compliance for the reception of a psychic conflict centered around his duties as a military policeman. Although it would have been possible for this soldier to display another form of conversion hysteria, it would have required a conflict in another area. It is inconceivable that his becoming blind like an airplane pilot, or paralyzed like a foot soldier, could have solved his problems. Even paralysis of his left hand would have been illogical and ineffective. In that event, the chances are that the military policeman would have remained on duty and, being left handed, he would have suffered in vain.

The patient's conflict was connected with his job, where his self-esteem and financial security became endangered by anticipated failure and consequent reduction in rank. The only way out of this situation was by inability to perform the necessary duties of saluting and handling a gun with his right hand. This meant that he could not carry out important functions of a military policeman. In addition, as an individual, his right hand was the least important of the two, being left-handed, he was able to satisfy his customary needs. His choice of symptom was indeed the least disadvantageous and at the same time the most rewarding. At the expense of only minimal discomfort, the patient achieved a maximal benefit by the removal of an anxiety-producing situation.

### SUMMARY

A case of hysterical paralysis of the right hand in a left-handed military policeman is presented, and the specific form taken by

the disease in relation to the assignment is stressed. An important function of the assignment and the function least important to the individual—use of the right hand—fell prey to the process of conversion. The choice of this hysterical symptom seems to have been determined by the maximal benefit gained in return for the minimal discomfort suffered under the condition existing.

#### THE GP AND AVIATION MEDICINE

Airline passengers almost never come in contact with the aviation medical specialist and for good reason he is concerned with the medical and allied problems of aviation—to make flight safer, more reliable and more comfortable for more people. Medical practitioners in private practice are the ones to whom prospective passengers turn. Several excellent texts and references on aviation medicine are readily available. Chief among these are Armstrong's "Principles and Practice of Aviation Medicine," McFarland's "Human Factors in Air Transportation," "Aviation Medicine Practice" prepared by the Bureau of Medicine and Surgery of the Department of the Navy and the U S Air Force's "Flight Surgeon's Manual."

## A MESSAGE FROM THE A M A

During May and June, the House and Senate Joint Committee on Atomic Energy held eight days of public hearings on the nature of radioactive fallout and its effects on man. The hearings covered, in detail, the whole cycle of fallout from its inception in the detonation of nuclear weapons, through its scattering about in the atmosphere and descent to earth, and finally its uptake by and effect on human beings, animals, and vegetation. Some fifty experts were invited to present scientific testimony ranging from physics to pathology and from geology to genetics, as it relates to fallout.

One point the Committee was interested in was whether scientists, many of whom are employed by Government agencies, felt free to work and exchange information in the sciences related to fallout. The weight of the testimony was that such freedom exists. Another point the Committee was interested in, and one on which the testimony was not so satisfying, according to the Committee report, is whether or not information on fallout and its effects is reaching the public. Information on the biological effects of radiation has been presented to the public in widely read reports by the British Medical Council and by the National Academy of Sciences. These reports contain some information directly applicable to the fallout question.

In its summary of key points, the Joint Committee outlined seven general observations made on the results of the hearings. They are as follows:

1 **Origin of Fallout** It was pointed out that all nuclear explosions can be expected to produce some radioactive materials. However, certain kinds of explosions produce very much less radioactivity than others. Although there is no such thing as an absolutely "clean" weapon (that is, there is no such thing as a nuclear weapon detonation completely free of accompanying radioactivity), the amount of the radioactivity produced can be substantially altered in relation to the size of the explosion.

2 **Distribution of Fallout** There was substantial, but far from complete, agreement on what happens to radioactive debris produced in man's environment, how much is there now, how and

From the Council on National Defense of the American Medical Association. The views and opinions expressed are not necessarily those of the Department of Defense.

—Editor

where it is distributed, and how much is in man himself. There was considerable evidence presented to indicate that in no part of the atmosphere is fallout uniformly distributed and that, therefore, the effects of fallout on the world's population could not necessarily be expected to be uniform.

**3 Biological Effects of Radiation** There was general agreement that any amount of radiation no matter how small a dose, increases the rate of genetic mutation in a population. There was on the other hand, a difference of opinion as to whether a very small dose of radiation would produce, similarly, an increased incidence of such somatic conditions as leukemia or bone cancer, or a disease of life expectancy, in a population.

**4 Tolerance Limits** There was general agreement that there is a limit to the amount of radioactivity and, hence, to the amount of fission products that man can tolerate in his environment. The extent to which existing and future generations will be affected by man made radiation was shown to be intimately tied to certain decisions, moral as well as scientific.

**5 Effects of Past Tests** It was clearly shown that man's exposure to fallout radiation, including strontium 90, is and will be in general small, *for the testing already done*, compared with his exposure to other "normal background" sources of radiation (a fraction of 1 to 10 per cent), and even compared with variations in "normal background" sources. But it was not agreed on how this information should be interpreted.

**6 Effects of Future Tests** There were differences of opinion on how to forecast the consequences of further testing. The differences hardest to reconcile appear to be those concerning the biological effects of radiation. Pending a resolution of differences, it would appear from the information presented, that the consequences of further testing over the next several generations at the level of testing of the past five years could constitute a hazard to the world's population.

**7 Effects of Nuclear War** The catastrophic nature of the radiation effects from a multi weapon (atomic and hydrogen bombs) attack on the United States were clearly portrayed. Thus, of course, could be applied to any nation.

The 19 page Committee print of the report entitled "Summary Analysis of Hearings May 27 29 and June 3 7, 1957 on the Nature of Radioactive Fallout and Its Effects on Man" was printed by the U S Government Printing Office for the use of the Joint Committee on Atomic Energy. Those desiring a copy of the report may make request through this source and reference.

## MEDICAL OFFICERS OF 16 COUNTRIES GIVEN GRADUATE COURSE BY NAVY

Twenty eight medical officers from the navies of 16 friendly nations on 8 November will complete a two months' graduate course in medical management and preventive medicine at the U S Naval Medical School, Bethesda, Md. The courses are being given under the supervision of Captain Calvin B Galloway, MC, USN, commanding officer of the School, under the Mutual Security Program.

First row left to right Lt Noriyuki Fujisaki Japan, Capt Chul Yu, Korea, Lt (jg) Tezel Burbanettin Turkey, Capt Prakob Chakurok, Thailand, Lt Luis Morel Dominican Republic, Comdr Luis Bello Vargas Peru, Col Hospicio L. Solidum Philippines, Lt S T Wang Taiwan, Maj Avelino U Tayog Philippines. Second row left to right Capt Virgilio S Zomara Philippines, Lt Comdr Mitsuo Wochi Japan, Lt Comdr Kyong Ilan Chong, Korea, Col Luigi Camponelli Italy, Lt Comdr Joaquin Diaz Gonzalez Roca Mexico, Lt Laborde Edg Titus Haiti, Lt Comdr Kamil Kusuoğlu Turkey, Lt Comdr Necati Keskin Turkey, Comdr C Y Su, Taiwan, Comdr Carlos Cepedo Chile. Third row left to right Capt. Calvin B Galloway MC USN commanding officer U S Naval Medical School, Comdr Akira Takagi Japan, Lt Antonio Venegas Chile, Lt Enzo Tarani Italy, Lt (jg) Francisco J Garcia Puig Cuba, Commodore Johan Greve-Brun, Norway, Lt Senl Wattasingh Thailand, Comdr Hans Bierbaum Germany, Comdr Orban Mordalga, Turkey, Lt Comdr Bruce W Halstead MC USNR staff officer U S Naval Medical School. (Lt (jg) V N Ha, Viet Nam is not in the photograph.)

Didactic work is being supplemented by visits to numerous military and civilian installations. The students were graciously received by the Honorable Dr Frank B Berry, Assistant Secretary of Defense (Health and Medical), and were impressed by the complexities of operations observed in the Pentagon. They also visited the clothing center of the U S Marine Corps and the U S Army at the Quartermaster Corps Depot, Philadelphia, Pa., the U S Naval School of Aviation Medicine, Pensacola, Fla., the experimental diving unit of the Naval Gun Factory, Washington, D C., and the United Nations building in New York.

## ADMIRAL HOGAN VISITS U S S SEAWOLF

Rear Admiral Bartholomew W. Hogan (right), Surgeon General of the U S Navy and Chief of the Navy's Bureau of Medicine and Surgery, is shown aboard the nuclear powered submarine *Seawolf* recently in Groton Conn, as Lieutenant Commander John H. Ebersole the ship's medical officer, demonstrates the airplane type controls used in the control room. Admiral Hogan also paid informal visits to the U S Naval Medical Research Laboratory and the Station Hospital, Submarine Base, during his stay in New London, Conn.

Admiral Hogan was elected to the Board of Trustees of the American Hospital Association at the 59th annual meeting in Atlantic City N J. He has served as delegate at large of the American Hospital Association and as a member of the American College of Hospital Administration.

## GENERAL HEATON HONORED BY BRAZILIAN OFFICERS IN WALTER REED CEREMONY

Brigadier General Arthur Augusto Alcantara, Commanding General of the Central Hospital of the Army, Rio de Janeiro (left) and Colonel Paulino DeMello, Director of the Policlínica of the Army, Rio de Janeiro (right) recently presented a medal and diploma of honorary membership in the Brazilian Academy of Military Medicine to Major General Leonard D. Heaton, Commanding General of Walter Reed Army Medical Center. The Brazilian medical officers visited Walter Reed as part of a three week orientation and observation tour of the United States. Major General Silas B. Hays, the Surgeon General, U. S. Army, also was presented a medal of honorary membership at a ceremony in his office.

After leaving Washington, General Alcantara and Colonel DeMello visited DeWitt Army Medical Center, Fort Belvoir, Louisville (Ky) Medical Depot, Army, Denver, and the Brooke Army Medical Center, Fort Brooke, Texas.

## OFFICIAL DECORATIONS

The following awards have been announced by Departments of the Navy and Air Force since 1 August 1957

### Legion of Merit

Wayne O Kester Brig Gen USAF (VC)      Edward J Tracy Brig Gen USAF (MC)  
Olin F McIlroy Maj Gen. USAF (VC)      Mitchell M. Young Col USAF (MSC)

### Distinguished Flying Cross

David G Simons Maj USAF (MC)

ERRATUM It is regretted that in printing the article by Dr. Charles G. Wilber on "Water Requirements of Man" that was published in the August 1957 issue of this Journal an error was introduced in the next to last line on page 1124. The word "Barometric" should have read "Vapor"—Editor

## CORRESPONDENCE

Honorable Frank B. Berry, M. D.  
Assistant Secretary of Defense  
Washington, D. C.

Dear Dr. Berry:

During these times of economy drives in Government, I would like to take this opportunity to bring to your attention the splendid work that is being done at the Armed Forces Institute of Pathology not only for the military but also for the civilian population.

The Armed Forces through its staff pathologists have given consultation services to the pathologists in all communities. They have also served as a clearing house for information of particular value to certain geographical locations. Their publications that are available are outstanding and are available at a nominal fee. The refresher courses offered at the Institute to military and civilian pathologists are a credit to the Armed Forces.

Through the guidance of extremely capable men who have headed the Institute particularly since the postwar years and now under the competent direction of Captain William M. Siliphant, MC, USN, the organization has reached the point of international recognition. On the domestic scene, it has provided material for seminars for medical societies such as the American College of Pathologists and many others.

Although a Government agency, the Institute is in no way in conflict with civilian institutions. It is unfortunate indeed that the work of the Institute is not brought to the public as a fine example of how money is being spent by the military to promote health and the welfare of the country.

I would therefore like to take this opportunity to express through your office my sincerest appreciation to the Director of the Armed Forces Institute of Pathology for making available the full consultation services of the staff pathologists to this community.

MARVIN N. SOLOVY, M. D., F. A. C. P.  
Pathologist, Newcomb Hospital  
66 South State Street  
Vineland, N. J.

## Reviews of Recent Books

**STRESS AND STRAIN IN BONES** Their Relation to Fracture and Osteogenesis by *I. CAYOR LINTS* Ph D American Lecture Series, Publication No 204 The Bannerstone Division of American Lectures in Medical Physics, edited by *Otto Glasser* Ph D 245 pages illustrated Charles C Thomas Publisher Springfield Ill, 1957 Price \$6.50

This book is a detailed report of the more significant experimental investigations on stress and strain in bones. The author has carefully reviewed the literature on this subject and has critically weighed the conclusions drawn by many investigators, including himself. The 15 chapters are devoted to the engineering principles involved and the results obtained in many investigations to determine the tensile, compressive, shearing, torsion, bending, and fatigue strength of bones of man and other animals. Conclusions and opinions concerning the significance of the results of these studies are presented briefly. A glossary of engineering terms is included and will assist the clinician in his effort to glean a significant fact to help him in the practice of orthopaedics. The list of references is comprehensive.

The average reader may be startled to learn that one investigator elected to study bone "of an ox six years of age, a mule, and the femurs of two women 42 and 90 years of age," and he may not be able immediately to grasp the importance of studying the comparative breaking strength of the bones of Polish cows and Dutch cows, but he will certainly be rewarded by learning many important facts to add to the little understood role of stress and strain in fracture productions as well as healing. The investigator will find much to interest him in this timely review and he should find it to be an indispensable reference. —CLIFFORD A. STEVENSON Capt MC USN

**CLINICAL CARDIOPULMONARY PHYSIOLOGY**, Sponsored by the American College of Chest Physicians, edited by *Burgess L. Gordon* M D et al 768 pages 248 illustrations 32 tables Grune & Stratton, Inc New York, N Y, 1957 Price \$15.75

Under the sponsorship of the American College of Chest Physicians, an editorial board headed by *Burgess L. Gordon* M D, and consisting of *Albert H. Andrews, Jr*, M D, *Alvan L. Barach*, M D, *John F. Briggs*, M D, *Edwin R. Levine*, M D, *George R. Meneely*, M D, *Hurley L. Morley*, M D, *Maurice S. Segal*, M D, and *Harold G. Trimble*, M D, has effectively assembled 39 subjects dealing with cardiac and pulmonary physiology, largely as they relate to clinical medicine today. The 52 contributing authors are recognized authorities in their field.

Here in a single volume is a summarization of clinical and physiologic data pertinent to cardiac and pulmonary problems that is so comprehensive it at once seems a little overwhelming. Although the primary purpose of this volume is to provide an understanding of altered physiologic mechanisms it would be unjust to fail to mention that much space is advantageously given to clinical descriptions, diagnostic studies and therapeutic measures particularly in so far as they alter disease states.

Almost of necessity there must be some overlapping of subject matter in the various sections and, as would be expected, this has created repetition of some basic and applied data. While adding to the bulk of the work this very repetition has immeasurably enhanced its value as a reference source inasmuch as each contributing author's section stands alone. This, of course, obviates the need for skipping from one section to another in search of basic or explanatory data. There has long been a great need for a collection such as this for it is without precedent and there is no comparable volume of its scope available today.—FRANK L. MILLER Lt Col. MC USA

**OBESITY Its Cause Classification and Cure** by E. Philip Gelvin, M.D., F.A.C.P. and Thomas H. McGavack, M.D., F.A.C.P. 146 pages. Paul B. Hoeber Inc. Medical Book Department of Harper & Brothers, New York, N.Y. 1957. Price \$3.50.

This volume represents a 10-year experience in an outpatient clinic devoted solely to the management of obesity. Chapters are devoted to pertinent basic biochemistry and consideration of endocrine and metabolic factors but the best section is undoubtedly the one dealing with diet. The authors emphasize correctly the necessity for constructing a weight reducing diet that will establish proper eating habits after termination of treatment and discuss the deficiencies in the use of the high protein diet and the Pennington high fat diet with this in mind. In attempts to arrive at a standardized reducing diet such factors as expense, availability, popularity and variability have been carefully considered. Emphasis is placed on the size of portions rather than adherence to calories per se.

Three chapters are devoted to the use of various drugs in the treatment of obesity. The enthusiasm in this text for amphetamine derivatives is not shared by many other workers in the field but appears justified on the basis of a fairly extensive objective clinical study which is well documented. Other subjects such as the use of cortisone or prednisone in the therapy of special forms of obesity should be viewed with a high degree of skepticism and are not well substantiated by figures or case material although reference is made to some thirty patients.

The bibliography covers 131 references to various aspects of the subject and serves as an excellent springboard for more detailed study. There were however no references to psychologic factors in the genesis of obesity although an impressive literature has accrued on this

subject. Only one page is devoted to this subject in the text and clearly, little is said about the psychological factors that play an important role in the patient's ability to proceed with treatment effectively. This is perhaps a reflection of the nature of our patient practice.

This book is aimed at the general practitioner or internist and the authors are to be commended for its simplicity, directness, and emphasis on the practical aspects of therapy. If it does nothing else but illustrate our extraordinary lack of knowledge about this important subject, it will have served its purpose. —ALL J. KOSEFF Capt. MC USA

**TEXTBOOK OF PATHOLOGY With Clinical Applications** by Stanley L. Robbins, M.D. 1351 pages illustrated W. B. Saunders Co. Philadelphia, Pa. 1957. Price \$18.

In the preparation of this textbook of pathology, Dr. Robbins set out to produce a volume particularly for students and clinicians. He has not only accomplished this but also written a book which will be useful to pathologists. The subject matter is handled in logical sequence beginning with the normal, going through etiology, pathogenesis, pathologic alterations, and ending with clinical correlations. General pathology and principles are presented in the early chapters to be followed by organ and systemic pathology. The subject matter of pathology is covered quite fully with major emphasis placed on the commoner lesions. Uncommon disorders might occasionally be given greater prominence but of course there is a limit to the size a text may assume. Some chapters have been prepared by specialists in particular fields.

The book is well bound and printed accurately in clear, legible type on good quality paper. Numerous illustrations of superb quality are employed throughout the text. References at the end of some chapters might well be expanded in number but those given have been well chosen. The index, a most important part of any text, is extensive and permits ready location of desired material.

One of the most outstanding accomplishments of this book is its easy readability and ready comprehension. Dogmatism is avoided throughout, controversial and unsettled problems are discussed fully, and various opinions presented with attempts to reconcile the differing views wherever possible. Clinical correlations and applications are particularly useful. This book is to be recommended highly for medical students and clinicians, and the practicing pathologist will also find it a source of much valuable information. —HOWARD A. VAN AUKEN Col. MC USA

**PRACTITIONERS' CONFERENCES** Held at The New York Hospital-Cornell Medical Center. Volume 6. Edited by Claude E. Forkner, M.D., F.A.C.P. 378 pages illustrated. Appleton-Century-Crofts, Inc., New York, N.Y. 1957. Price \$6.75.

This is the sixth in a series of conferences held at the New York Hospital-Cornell Medical Center and presents a variety of entities in panel form. There are 15 chapters dealing with such

sified subjects as "Should Parents be Told the Truth About Serious Illness" to discussions on cancer of the thyroid prostate esophagus lung and bone. Panel discussions are also presented on heart disease dermatology endometriosis encephalitis and parkinsonism gout trichinosis and portal hypertension. A chapter on Consultations with Anesthesiologists provides excellent coverage of current thoughts on the types of anesthetic agents employed their effects on the body and their dangers.

The presentations are spirited and are aimed at the practical side of the practice of medicine. In several chapters the discussants refer to slides they are showing but in such a fashion that it is of little or no benefit except for those physically present. A few words of edited summary would save space and readers' time at these points. All the pertinent facts elicited in the discussions are aptly and systematically summarized at the conclusion of each chapter. In addition a small but well chosen bibliography on the subject is also listed. This series of conferences would be a welcome addition to a general practitioner's library and to hospital and medical school libraries. It is too diversified for the specialist. —JULES J McNERNEY Lt Col MC USA

**HANDBOOK OF LEGAL MEDICINE** by Louis J Regan M D LL B and Alan R Moritz M D. 201 pages illustrated. The C. V. Mosby Co. St. Louis Mo. 1956. Price \$3.90.

The first 95 pages of this book concern relationships between the physician the patient and the law. The balance of the volume deals with scientific medicolegal investigations. In addition, there is a glossary of 12 pages, a list of references for more detailed information, and a well compiled index.

This small compact volume covering the more important highlights of medicolegal ramifications is well written in clear and distinct form with good illustrations. It should be read by all physicians and dentists as well as students in both professions. The book would be excellent reading as well for nurses particularly nurse supervisors and hospital administrators. It has a wealth of knowledge condensed into readily readable size. —FRANK P GILMORE Rear Adm. MC USN

**THE FAMILY IN PSYCHOTHERAPY** by C. F. Midelfort, M D. 203 pages. The Blakiston Division McGraw-Hill Book Co. Inc. New York N Y. 1957. Price \$6.50.

In this compact volume the author describes his experiences with psychiatric patients admitted to the La Crosse Lutheran General Hospital. In this institution relatives have long been allowed to stay with mental patients to assist in occupational recreational and insulin therapies. Dr. Midelfort reports on patient treatment in which relatives take part in therapeutic interviews.

The book is largely composed of case histories with special emphasis on schizophrenia depression paranoid illness psychopathic per-

personality and psychoneurosis. The reader will find innumerable the provoking clinical observations depressed patients are the victims of the restricting cultural traditions of families of uniform ethnic religious and family backgrounds. Also the psychiatrist cannot approach the paranoid patient directly but can do so through common activities with the patient's children. The thesis which Dr. Midelfort's case histories illustrate is that mental illness in the family is a product of genetics and of social and cultural heredity. The factors that play a dynamic part in mental illness are at work in the family and to treat only one patient from the family without the others can influence only a part of the difficulty leaving much untouched.

Dr. Midelfort's book is a significant contribution to the growing trend toward greater inclusion of the patient's family milieu in psychotherapy. In addition it is an excellent illustration of the advantages of psychiatric treatment within the setting of the general hospital. One cannot fail to be impressed with Dr. Midelfort's many successfully treated cases (although his failures are discussed very candidly) and with the modest expenditures of the therapist's time which were often involved. There is much in the area of practical handling of patients and families which has been omitted from the book: one patient's husband and small son remained in the hospital with her during her acute psychosis, a therapeutic maneuver which must have required a great deal of flexibility on the part of the staff.

Dr. Midelfort has made an important contribution to psychotherapy and his book is strongly recommended for all concerned with the treatment of mental illness.—JOHN C. WEBER, Lt. Col. USAF (MC)

Zinsser's BACTERIOLOGY by David T. Smith, M.D., Norman F. Conant, Ph.D., et al. 11th edition. 953 pages illustrated. Appleton-Century-Crofts, Inc., New York, N.Y., 1957. Price \$12.

This is a new edition of a time-honored publication that has always been a valuable asset to students, instructors, bacteriologists, epidemiologists, and laboratory staffs. The objective of the original authors, Hiss, Zinsser, and Bayne Jones, has again been presented to this edition, extending not only the biologic characteristics of the organisms but also the reactions of living tissues to bacteria and their metabolic products. In this manner the text becomes of equal value to the bacteriologist, the epidemiologist, the public health profession, and to the student. The philosophy of the presentation has been to substantiate the basic biologic approach to bacteriology, and at the same time to emphasize the public health significance and the practical clinical importance of certain of these biologic characteristics of organisms. Epidemiological characteristics also are included in each presentation, thus extending the value of this publication.

This edition has undergone extensive revisions and the interest of presenting as completely as possible the most recent information on each subject. W.

the advent of the tenth edition nearly twice as many significant publications in the field of microbiology have appeared as in the previous five years. Advancement in the field of bacterial physiology, immunology, and viruses have been incorporated in this text. A new chapter covering the academic aspects of blood grouping and immunohematology also has been added. This edition also includes information on the susceptibility effects of the newer antibiotics on specific organisms. Each chapter closes with an excellent list of references.

This text is an excellent consolidation of technical material derived from current investigations on each group of organisms. It is highly recommended for inclusion in the technical libraries of laboratories for basic science students and for individuals concerned with epidemiology or diagnostic laboratory facilities.

—WILLIAM H. LEE Lt Col USAF (MSC)

**THE DIAGNOSIS AND TREATMENT OF ENDOCRINE DISORDERS IN CHILDHOOD AND ADOLESCENCE** by Lawson Wilkins M D 2d edition 526 pages illustrated Charles C Thomas Publisher Springfield Ill 1957 Price \$17.50

This classical work in pediatric endocrinology has been extensively revised and expanded in this second edition. Written and presented for the clinician, the case reports, original pictures of clinical material, and easy readability greatly enhance the value of this book. Of particular interest in this revision are the newer diagnostic methods, the discussions of sex chromatin, metabolism of carbohydrates and calcium phosphorus. The chapter on the adrenogenital syndrome has been revised in the light of the therapeutic response to cortisone. The one on the hormone assays and tests and their diagnostic applications and limitations is exceedingly well presented. Differential diagnosis is stressed. There is an extensive bibliography at the end of each chapter which is subdivided according to the subjects with which they deal. This most authoritative and up-to-date presentation of endocrinology written by an author who has made notable contributions in this field should be in the library of those engaged or interested in the treatment of endocrine disorders in the pediatric age group.

—ERNEST R. MOELLER Capt MC USN

**THE NURSE AND THE OUTPATIENT DEPARTMENT** by Audrey Windemuth R N B S 580 pages The Macmillan Co New York N Y 1957 Price \$6.50

The author with her vast experience has a comprehensive knowledge and understanding of the subject of this new book which deals exclusively with the nurse and the outpatient department. Her style of writing makes for easy and enjoyable reading and arouses an interest to read further. The position of the outpatient department in functioning between the hospital and the community health activities is clearly and concisely outlined. While all outpatient department activities are covered briefly, particular emphasis is placed on teaching patients better health measures which will aid in promoting a healthier com-

units. The relationship of the doctors, dietitian, physical therapist, occupation therapists, social workers, and public health workers related to the total patient care is treated in a manner that clearly depicts each role.

Since the age of rapidly expanding medical care through outpatient service the nursing profession has been in need of an up-to-date textbook for teaching and training personnel. Miss Warden has very well filled this need most admirably. It is recommended as a reference for graduate nurses concerned with outpatient nursing and should be of particular value to all schools of nursing. It contains an excellent index with cross reference to facilitate its use.

—ALICE L. SOLT, MS, ANCC USA

**MAGNETIC REMOVAL OF FOREIGN BODIES** The Use of the Alnico Magnet in the Recovery of Foreign Bodies from the Air Passages, the Esophagus, Stomach and Duodenum, by *Murdock Equen, M.D., F.A.C.S.* 94 pages. Illustrated. Charles C. Thomas, Publisher, Springfield, Ill. 1957. Price \$4.50.

The author has drawn upon more than 12 years of experience with Alnico Magnets in removal of ferrous alloy (magnetic) foreign bodies from the tracheobronchial tree, esophagus, stomach, and duodenum. His monograph is written in an informal, conversational style and organized into seven short chapters. Much of the contents of the book is devoted to case histories depicting the various situations that confront the patient, parents, physician, and the specialist when foreign bodies become lodged in the air passages or the upper gastrointestinal tract. Photographs of the various modifications of the small semipermanent magnets utilized for removal of magnetic foreign bodies from various levels in the air passages and upper gastrointestinal tract are included together with an ample array of reproductions of roentgenograms demonstrating almost every conceivable foreign body problem.

Dr. Equen reports phenomenal success employing his technique with the magnet under fluoroscopic guidance in over two hundred cases, although an occasional unsuccessful case is reported. This reviewer does not fully share in the policies of the author as to the early removal of small foreign bodies from the stomach and duodenum which, by and large, are prone to continue their harmless passage on through the gastrointestinal tract within a few days. It is of interest that of 19 metallic foreign bodies retrieved from the duodenum, 10 had been swallowed on the day of removal. Notwithstanding Dr. Equen's keen advocacy of magnetic methods, he does include remarks on disadvantages, contraindications, and precautions that are felt to be quite logical.

This book is recommended to professional libraries that provide references for any sizable group of physicians; it can be read with interest by the general practitioners, general surgeons, otolaryngologists, bronchoscopists, gastroenterologists, pediatricians, and radiologists. —JOHN M. SALYER, Col., MC USA

**DEVELOPMENTAL ABNORMALITIES OF THE EYE** by Ida Mann C. B. E.  
M. A. (Oxon) D. Sc. M. B. B. S. (Lond) F. R. C. S. (Eng) F. R. A.  
C. S. 2d edition 419 pages illustrated J. B. Lippincott Co Phila-  
delphia Pa. 1957 Price \$15

This second edition of what has become a classic in ophthalmology deserves the praise which it will continue to receive. A subject not appealing to many clinicians is tied in so closely with problems of practice that the book is fascinating to read. It progresses logically from the discussion of the development of the eye from conception through its intrauterine phase and then through life. Finally it considers those senile changes which are based on an hereditary background.

The discussion in sequence of events pertaining to individual structures is especially valuable for reference purposes. The anatomy is reviewed in detail in the process and the differentiating points between developmental and disease processes are emphasized. This results in necessary duplication of material but makes reference much easier and conditions more readily understood. The illustrations are excellent and abundant.

This book will be especially valuable to the ophthalmologist since it was written by an ophthalmologist with that goal constantly in mind. It is highly recommended for inclusion in the libraries of ophthalmologists, geneticists, pediatricians, psychiatrists, neurologists and others interested in abnormalities of the eye.

—VICTORIA BYRNES Brig Gen. USAF (MC)

**A MANUAL OF PHARMACOLOGY and Its Applications to Therapeutics and Toxicology** by Torald Sollmann M. D. 8th edition 1535 pages W. B. Saunders Co Philadelphia Pa. 1957 Price \$20

Earlier editions of this manual have been in common use longer than almost any other textbook in the medical sciences except of course Gray's Anatomy yet this volume is by the same author who in 1917 wrote the first edition which has since been an important guide to the medical student and especially to the pharmacologist.

As an aid to the student the sections in ordinary type in this edition as in earlier ones present "the material all students should aim to know" while the sections in small type contain important reference information. The bibliography of approximately 4000 references is restricted to those publications since 1939. Earlier references are in other editions. Recognizing the difficulties of classifying drugs entirely by chemical nature or by physiologic action the author has used both such as "sulfonamide compounds" and "convulsant poisons." Most frequent use is made of a chemical classification. There is no division into chapters.

The professional pharmacologist will continue to find the book very useful because of its wide scope and useful references. The medical

student and those in related fields may find the failure to follow more common arrangements and the lack of chemical information disadvantageous. The space devoted to individual drugs bears little relation to their frequency of use. As instances, several times as much space is devoted to oil of turpentine as to meprobamate (consistently referred to as meproamate) which is discussed with 16 lines of small type, the discussion of strychnine occupies eight pages and that of setorinin less than one half, approximately the same amount of space is devoted to the use of bismuth in syphilis as to the use of penicillin in this disease.—PAULA SMITH Col USAF

CIBA FOUNDATION SYMPOSIUM on the CHEMISTRY AND BIOLOGY OF PURINES. Editors for the Ciba Foundation G. E. W. Wolstenholme O B E M A M D B Ch. and Cecilia V O'Connor B Sc 327 pages with 124 illustrations and structural formulae Little, Brown & Co Boston Mass 1957 Price \$9

In its treatment of the synthesis and biological activity of purines, this volume attains the high level of achievement which has characterized the recorded proceedings of previous Ciba Foundation Symposia. It can be expected to receive the careful attention of organic chemists concerned with the structure and synthesis of purines and of purine derivatives of known or potential biological significance. The collected papers also contain much that will be of similar importance to persons interested in fundamental research on cancer, enzymes and the development of new chemotherapeutic agents.

Material pertaining to synthetic organic chemistry is concentrated upon the preparation of purines and of related compounds intended for testing as chemotherapeutic agents (e.g. in acute leukemia) compounds which might be expected to occur in the course of the *in vivo* oxidation of purines, and those which might provide an improved understanding of nucleoside structure (e.g. putomycin). Analogous subject matter is concerned with determinations of hydroxy purine structure, the chemistry of new purines of the B<sub>12</sub> vitamin series and the chemical transformation of purines into pteridines.

On the biochemical side there is an extended review of the recently enhanced state of our knowledge concerning purine biosynthesis, a discussion of the available evidence relative to the hypothesis that xanthine oxidase is a "key enzyme" in controlling the pool of biological purines and a consideration of the relationship between biological activity and alterations in the molecular structure of puromycin. Finally there is a paper on the biochemistry of 6-mercaptopurine followed by a discussion of the clinical limitations of 6-mercaptopurine therapy, based upon the study of 18 patients with acute leukemia and of 12 patients in the terminal stages of chronic myeloid leukemia. Only 7 of the former were treated with 6-mercaptopurine alone 3 of these died without achieving remission. Seven of the 12 chronic myeloid leukemia patients received no benefit from treatment with 6-mercaptopurine.—THADDEUS J DOMANSKI Col USAF (MSC)

The Early Diagnosis and Treatment of ACOUSTIC NERVE TUMORS by J Laurence Pool M D and Arthur A Pava M D American Lecture Series Publication No 303 A Monograph in American Lectures in Surgery edited by Michael E DeBakey M D, and R Glen Spurling M D Neurosurgery Division, edited by Barnes Woodhall M D 161 pages illustrated Charles C Thomas, Publisher Springfield Ill 1957 Price \$5.50

This is a thorough well written study of a relatively infrequent type of brain tumor of primary interest to neurosurgeons. It is also of diagnostic interest to general practitioners neurologists radiologists otolaryngologists and internists because it is this group of physicians who most frequently have the opportunity of making the all important early diagnosis.

The chapters relative to the differential diagnosis signs symptoms and diagnostic procedures currently employed are especially to be commended because of their completeness. In compiling the frequency of the various signs and symptoms the authors not only utilize their own series of 122 patients but also those of five other large series. The other important chapters are devoted to operative intervention with presentation of data on total versus subtotal removal operative technique and postoperative management. Mortality complications and sequelae from operative intervention are enumerated and analyzed with due emphasis on facial nerve paralysis and its subsequent treatment.

—WILLIAM J JAMES Capt MC USA

BASIC NUTRITION by E W McHenry M A Ph D F R S (C) 389 pages J B Lippincott Co Philadelphia Pa 1957 Price \$5

Practicability is the keynote of this book. Historical data sources and requirements of the various nutrients are presented in a clear concise and factual manner. Emphasis throughout is on the need to consider the nutritional requirements of the individual. Arbitrary adherence to a prescribed dietary standard without giving thought to the factors affecting the requirements is discouraged. Flexibility in the selection of food to achieve adequate nutrition is recommended rather than advocating a rigid set of rules to follow. While it is shown that the nutritional requirements might be met by the use of a very simple selection of food this is not advised from a practical point of view.

Special diets receive only brief notice both as to types of diets discussed and as to space devoted to this subject. Here too caution is advised. The student might well heed the advice that there is benefit to be gained by both the hospital and the patient from limiting special diets to those that are really necessary. Attention is directed to the pitfalls of indiscriminate use of restricted diets. Dietary standards principally those of the United States and Canada are explained and omissions from these standards are pointed out. The evaluation of nutritional studies gives an insight into the value of these studies. From this introduction to the study of nutrition the student should be well aware of the many facets of nutritional education.

—HELEN M DAVIS Lt Col AMSC USA

**PEDIATRIC CLINICS OF NORTH AMERICA** Symposium on Pediatric Hematology, May 1957. *Wolff H. Zuelzer* M.D., Consulting Editor. 591 pages. Illustrated. W. B. Saunders Co. Philadelphia Pa. 1957. Price \$15 per year of 4 books issued quarterly. Sold only by a year of four consecutive numbers.

Previous publications of these clinics have been excellent and this volume is no exception. The consulting editor states in the foreword that no attempt was made to cover the entire subject. Nevertheless most of the important aspects of pediatric hematology are covered expertly and concisely. The volume is obviously directed to those who have direct responsibility for the care of the child. The selected bibliography should make this a frequently consulted work. Deserving of special attention are the rational approach to the diagnoses of the pediatric anemias. Dr. Chown's refreshing style applied to the nonhemolytic anemias and the language of genetics provided by Dr. Neal. The logical and practical approach made by Dr. Wheeler to exchange transfusion in erythroblastosis is alone worth the price of the book.—*LEO J. GIPPERT* Col. A.C. USA

**THE SPECIALTIES IN GENERAL PRACTICE** edited by *Russell L. Cecil* M.D. and *Howard F. Conn*, M.D. 2d edition. 780 pages. Illustrated. W. B. Saunders Co. Philadelphia Pa., 1957. Price \$16.

The second edition of this book first published in 1951, consists of 14 chapters each dealing with a different specialty field and written by a senior specialist in that field. Its purpose, to quote the editor, is to provide "a sort of ready handbook for the busy physician in which he might find brief and practical descriptions of how to handle the less serious problems in the various special fields." The fields of internal medicine and general surgery are not included, presumably on the basis that general practitioners are already familiar with the commoner conditions in these fields. The emphasis in the book is not on recent advances in the fields but rather on abbreviated textbooks dealing with the common conditions in each field.

Some of the faults in this book are inherent in the basic editorial design. The degree of compression of material required by the size and scope has frequently resulted in a stripped skeleton of no value to anyone such as the 30 lines on gout or the single page on Port's disease in the section on orthopedic surgery. This brevity approaches the danger point in many areas where essential information is omitted. In the section on pediatrics, neomycin is advocated for infant diarrhea with no warning of its toxicity and no suggestion for a stool culture prior to instituting therapy. Other faults are even less easy to explain or condone. In the discussion of dog bite and rabies prophylaxis in the section on pediatric immunization, there is no mention of the existence of rabies antiserum although this is an essential part of modern management. In the section on nose and throat there is no mention of ear infections as an indication for tonsillectomy but tonsillectomy is recommended to eradicate foci of infection. Other faults are found even in the absence of any other.

section septic sore throat is vaguely considered as being due to a variety of secondary invaders following a viral infection. The statement is made that beta hemolytic streptococci are implicated in only 25 per cent of the cases. In treatment sulfa drugs are considered of equal value with penicillin and doubt is expressed as to whether every infection should be treated with antibiotics at all. Neither rheumatic fever nor the suppurative complications of streptococcal diseases are mentioned.

This book is not recommended. The sections which are accurate and up to date are too brief to be of any real value and others contain misinformation — CHRISTIAN GROVBECK, Jr. Lt Col MC USA

SCOVILLE S. THE ART OF COMPOUNDING by Glenn L. Jenkins, Don E. Francke, Edward A. Brecht and Glen J. Sperandio. 9th edition. 551 pages illustrated. The Blakiston Division, McGraw-Hill Book Co., Inc. New York, N. Y. 1957. Price \$11.

This new edition of a standard work is greatly improved in several respects. Like former editions it concentrates on the study of compounding and dispensing and eliminates related but extraneous subjects such as manufacturing processes and administration of drugs. Every part has been revised and brought up to date. Several of the chapters have been completely rewritten and the work has been made more suitable for use as a textbook.

The authors have arranged the material so that the student progresses systematically from the simpler to the more complex problems of compounding and dispensing. They have kept in view two main objectives: first, to present the principles underlying each practice so that the student may understand the theories as well as perform the operations involved in compounding; and second, to illustrate the principles by prescriptions and exercises and to show their practical utility at the prescription counter. They have kept the volume to a convenient size by the omission of illustrations or subject matter that have become obsolete or belong properly in other courses and have added to its practical value by using illustrative examples drawn from actual practice. The section on incompatibilities is especially improved by the inclusion of many new items and is arranged so that it may be used by itself as a one term course.

The new chapter on ophthalmic solutions and the enlarged chapters on powders, capsules and effervescent salts, tablets, parenteral solutions, isotonic solutions, sterilization and infection and ointment and ointment type preparations are a few examples of the improvements and modernization to be found in the treatment of every subject. The authors deserve the thanks of both students and practicing pharmacists for the thought and labor they have expended in making this new edition so valuable as a textbook and work of reference.

—RUSSELL L. TAYLOR, Capt. MSC USN

FUNDAMENTAL OF CLINICAL PHYSIOLOGY by Paul S. Grollman, M.D., F.A.C.P., formerly illustrated, Charles C. Thomas, Publisher Springfield, Ill. 1956. Pp. 312.

This review of the fundamentals of neurophysiology is an excellent illustration of material the author has presented in the first year course in physiology at Harvard Medical School.

The basic mechanisms responsible for the special functions of the nervous system are discussed. The early chapters cover the membrane potential and the nerve impulse, electrical excitation of nerve, and action potentials in simple fibers and mixed nerves. After a discussion of the general physiology of receptor organs, the author discusses the various senses. A brief review of muscle physiology is included. Reflex activity in the nervous system is described at the various levels of organization. Cerebellar and cerebral cortical function is presented in considerable detail, as well as the interrelationships between various brain centers.

The bibliography is extensive and the reader may at times get lost in the barrage of names and dates that document nearly every paragraph. However, patience with these details will reward the student with a good orientation to "the better established facts of neurophysiology" as the author writes. This book will be of interest to medical students and persons entering the clinical fields of neurology and psychiatry.—ROBERT L. WILLIAMS, *M.D. (Harv.)*

CLINICAL PROCTOLOGY by J. Leeman, *Associate Professor, M.D., M.C., (Med.) M.D., F.A.C.S.*, 216 Wilson Ave., New York 10014. W. B. Saunders Co. Philadelphia, Pa. 1957. Pp. 312.

This is a practical, concise, and orderly presentation of proctologic precepts beginning with a discussion of pertinent anatomy and physiology, proceeding through diagnostic procedures, and describing the common anorectal diseases. Pre and postoperative care is thoroughly discussed, and congenital malformation, neoplastic disease, and anal pruritus are considered. The final chapter gives a brief discussion of miscellaneous subjects such as bowel management, enemas, laxatives, suppositories, fecal impaction and incontinence, and various diseases. The chapter on clinical proctoscopy is particularly good and includes black and white and color photographs made through the proctoscope.

Unlike much current scientific literature this book is written in an easy straightforward style which approaches personal teaching by the author himself. The illustrations and photographs are the perfect complement to the text material. The medical student will find this book complete and readily understandable. The house physician or practicing physician who reads it will find himself more confident (and of greater service) in his approach to proctologic problems. It is highly recommended for anyone who does or contemplates doing proctoscopic examinations or any type of proctologic treatment.

—JAMES H. STUART

**SOCIOLOGY Its Use in Nursing Service** by Gladys Sewell B S, R N  
Ph O and Paul Hanly Furfey Ph D LL O 4th edition 502 pages  
illustrated W B Saunders Co Philadelphia Pa 1957 Price \$5

This revised edition follows the general concepts of sociology and its application in nursing practice The first part is a general outline of a beginning course in first year college sociology followed by a discussion of the relation of health to social conditions The final part deals with the social conditions and problems the nurse may meet in the care of patients in hospitals clinics and in public health work The last three chapters deal with illnesses in the various age groups and the sociopsychologic factors to be considered in each

The text is written in terms which can be understood by the beginner in both sociology and nursing At the end of each chapter topics for discussion and selected references are listed The chapter on human groups should be particularly helpful to the beginner in developing an awareness of groups and subgroups within the social structure of a society and the social processes which make for unity or disunity in that society The authors have achieved their purpose in providing a helpful text for nursing students and the book should be well received

—CHARLOTTE R. RODEMAN Maj ANC USA

**ENCYCLOPEDIA GUIDE TO NURSING** by Helen F Hansen R N M A  
406 pages illustrated with 8 colored plates The Blakiston Division  
McGraw-Hill Book Co Inc New York N Y 1957 Price \$6

This volume of standard nursing textbook size is the result of an endeavor to fulfill the need for a reference book of definitions guiding principles brief summaries of subjects and explanations of techniques and procedures To make it of practical value to nurses scientific detail and terminology have been reduced The terms listed are those in current use in the medical field and afford the reader clear explanations of up-to-date medical techniques and nursing procedures Full discussion of topics is one of the strong points of the book Detailed nursing procedures are given in conjunction with definitions where applicable The illustrations are limited to a set of excellent colored plates of the skeletal muscular arterial and venous systems and of the viscera

The pronunciation guide is not complete Reference must be made to a standard dictionary The appendices include a list of commonly used abbreviations prefixes and suffixes and tables of elements equivalent centigrade and Fahrenheit temperatures and weights and measures The completeness of the definitions of the terms listed and the cross references indicated show the author's respect for detail This volume is intended as a reference book for nursing service

In comparison of Hansen's "Encyclopedia Guide to Nursing" and Taber's Cyclopedic Medical Dictionary the former would be a fine supplement to but not a replacement for the Taber volume If one volume is to be chosen for use by all levels in the medical field Taber's Cyclopedic Medical Dictionary would be of most value

—EMMA F HOUSTON Lt Col ANC USA

**DYNAMICS OF PSYCHOTHERAPY**, the Psychology of Personality Change  
Volume II by *Perceval M. Symonds* Ph.D. 440 pages Cune & Stratton  
Inc. New York, N. Y., 1957 Price \$6.95

This is the second book of a three volume series devoted to the principles and practice of psychotherapy. Whereas the first volume was concerned with basic viewpoints and with the nature of psychoneurosis, the present work deals elaboratively with the client-therapist relationship as it develops through the processes of transference, resistance, attraction, insight and identification. The third book will be concerned with various practical therapeutic procedures. All three volumes are intended both as texts for students of psychotherapy and as reference works for established practitioners.

Although the author's theoretical orientation is clearly visible throughout the exposition, little attention is paid to abstruse and speculative concepts as such. On the contrary, the principal merit of the book seems to this reviewer to be in the rich and detailed description, analysis, and interpretation of the client's therapeutic experience at the behavioral level. What actions and attitudes to expect, how to recognize them, what their motivations are, and what their significance is for the therapeutic process as a whole are skillfully discussed.

From all points of view this book is exceptionally readable. It is well organized and its literary quality is superior. An annotated bibliography of some 240 titles enhances its value as a reference. It would be a valuable addition to the libraries of physicians, psychiatrists, clinical psychologists, and others concerned professionally with counseling and guidance.

—ROBERT B. PAYNE Lt Col USAF (MSC)

**LAW EVERY NURSE SHOULD KNOW** by *Helen Creighton* B.S.N., R.N., A.B., A.M., J.D. 197 pages W. B. Saunders Co. Philadelphia, Pa. 1957 Price \$3.50

In this paper bound "handbook" the author has presented in a clear, concise, and nontechnical manner the various phases of law which every nurse should know or be familiar with. A valuable and most informative book, it is one of the few written for nurses on this subject as it pertains to the practice of their profession. A brief presentation of the structure of our government, the sources of law, and function of the courts is followed by the purpose and problems of licensure for both the practical nurse and the professional nurse. Contracts, including breach and termination of contracts, are discussed in order that the nurse will know her rights, duties, and liabilities regarding them.

The legal status of the nurse and her rights and liabilities in relation to her position and status are also discussed. In the chapter on negligence and malpractice, the author discusses and briefly the common acts of negligence and malpractice.

nurse's liability in regard to them. Torts and criminal acts from misdeemeanors to felonies which the nurse is likely to encounter are presented as well as her responsibility as a witness in legal procedures and the making of wills. The last chapter is devoted to the legal aspects of nursing in Canada. There is an excellent table of contents and a good index. Also following each chapter is a list of case references as well as general reference readings.

This book is one which every nurse should have in her possession as a ready reference regarding her legal rights, duties and liabilities.

—AILEEN E. BRUMMER, Maj, USAF (NC)

**ORAL DIAGNOSIS AND TREATMENT (Oral Medicine)** A Textbook for Students and Practitioners of Dentistry and Medicine by Samuel Charles Miller D.D.S., F.A.C.D., F.A.D.M. and 37 contributors with an introduction by Raymond J. Nagle D.M.D., F.A.C.D. 3d edition. 977 pages. 577 illustrations in black and white and 30 color plates. The Blakiston Division, McGraw-Hill Book Co., Inc. New York, N.Y. 1957. Price \$16.

An old light burns with new luster as Dr. Samuel Charles Miller's "Oral Diagnosis and Treatment" keeps pace with 10 years' advance of dental science. The new third edition, as were the two previous editions, will be a valuable aid to the accurate practice of dentistry. Dr. Miller has edited the work of 37 experts into an authoritative 30-chapter volume which is a specific guide to the scientific approach to oral diagnosis. The presentation is masterful and concise.

Although the title of this book includes the term "treatment," this aspect, as might be expected, runs second to the clean-cut work in diagnosis. Treatment is discussed more on a suggestive basis of an outline type. With the references included, it can be a satisfying guide to treatment. It would not be fair to expect to cover the field in both diagnosis and treatment in a single volume of less than one thousand pages. There is one amazing new chapter on "Identification Keys as Diagnostic Aids." This is "an organized plan of analysis" using as keys the parts affected coupled with the signs and symptoms. It is a clever and well-planned procedure. Making the key to unlock the "unfamiliar condition" is a fascinating process.

Dr. Miller's standard text has become a part of almost every dental practice. The added coverage of this new edition should make it even more useful to the profession. The chapter on aviation dentistry alone will endear this volume to many practitioners. Nine of the chapters are entirely new. More than ever, this book is the cornerstone for every dental library. —JULES D. KARTMAN, Lt. Col. USAF (DC)

## New Books Received

Books received by the *U. S. Armed Forces Medical Journal* are acknowledged in this department. Those of greatest interest will be reviewed in a later issue.

## Monthly Message

I am happy to report some early observations on Public Law 497 Medical and Dental Officer Career Incentive Act and Public Law 569, authorizing medical care for dependents of members of the uniformed services.

First as to Public Law 497 in all three services the resignations have diminished and applications for commissions as regular officers have increased. This is heartening because as this situation comes into balance the need for requesting physicians and dentists by mechanism of Selective Service decreases. As a result no calls are foreseen for 1958.

As to Public Law 569 this has now been in operation since December 7, 1956 under the executive direction of Major General Paul I. Robinson MC USA. General Robinson is well known throughout the civilian medical profession as well as the military, and has been carrying forward with a rare ability in matters pertaining to personnel which he possesses. Under his direction relatively few serious problems have arisen. He is collecting and tabulating these as they arise, and will make a report on the operation of this law to the consultant group appointed by the Secretary of Defense in the late spring. Doubtless changes will be necessary, but all of us hope that under the skillful direction of General Robinson these will be comparatively few and all designed to perfect the operation of the Act.

## Foreword

The *United States Armed Forces Medical Journal* is the medium for disseminating information of administrative and professional interest to all medical personnel of the Department of Defense. The Assistant Secretary of Defense (Health and Medical) and the Surgeons General of the several services invite all medical officers, dental officers, Medical Service Corps officers, Nurse Corps officers, and officers of the Veterinary Corps of the Armed Forces, and the medical consultants of the Army, Navy, and Air Force to submit manuscripts for publication in this journal.

## A SHIPBOARD EPIDEMIC OF ASIAN INFLUENZA

DAVID C. WHITE Lieutenant MC USNR

**A**N EPIDEMIC of Asian influenza occurred on the U S S *Valcour* (AVP 55). The ship was relatively isolated from external contamination once the initial contact had been made and the progression of this disease in a susceptible military population could be studied with a minimum of outside influences. The clinical impressions that the disease progresses in severity during a pandemic<sup>1</sup> and that lack of sleep and physical fatigue correlate with severity and sequelae<sup>2</sup> were examined. The severity of the epidemic was compared to the 1918-1919 pandemic as it occurred in military groups.

### EXPOSURE

On 27 and 28 June 1957, while returning from the Persian Gulf, the ship stopped at Aden, where there was an epidemic of Asian influenza. On 1 July the first case of influenza appeared among the crew. On the same day the ship met its relieving ship, the U S S *Greenwich Bay* (AVP 41) from which 11 men were transferred to the *Valcour*. Between 2 and 3 July, the ship traversed the Suez Canal and did not make any new contacts until it reached Naples, Italy, on 7 July. There was no Asian influenza in Naples at that time. No new cases appeared after 10 July and all cases were discharged by 14 July.

### DIAGNOSIS

An oral temperature of 102°F plus a history of chills, arthralgia, myalgia, and cough were criteria of admission into this

From Aviation Medical Acceleration Laboratory U S Naval Air Development Center  
Johnsville Pa

study. Of the 201 men on the ship 71 met all these criteria, yielding a total attack rate of 35.3 per cent. An additional 29 men exhibited symptoms and a temperature of over 99 F, which made it seem probable that they also had the infection. No attempt was made to check on the rest of the ship's company other than to make announcements in the Plan of the Day describing the prodromal symptoms and urging men with the symptoms to report to sick bay. The additional 29 men were those who felt ill enough to come to the sick bay of their own volition. With inclusion of these cases the attack rate was 49.8 per cent.

The 71 cases in this series were graded as to severity. Mild cases were defined as those without marked symptoms other than fever and with a duration of less than 4 days. Severe cases had more pronounced symptoms that lasted 5 to 8 days. Patients with secondary infections were those whose febrile course went from 101 or 102 F down to 99 F in 3 to 4 days and then after 6 to 8 hours returned to 102 F. These patients were given 500 mg of oxytetracycline four times a day as soon as this febrile trend was established, the fever in all but one case returning to 99 F in a few hours. Abnormal pulmonary sounds were noted in all these cases.

Patients were discharged after 36 hours of normal temperature. Only 2 of the 71 patients suffered relapses. All cases cleared without sequelae except for some patients who were left with a cough that gradually disappeared.

Table 1 gives a breakdown of the attack rates by severity for the total epidemic including the nonadmitted cases that were treated as outpatients.

TABLE 1. *Attack rate of Asian influenza in crew of 201 by severity*

Severity	Number	Pct cent
Ambulatory	29	14.4
Mild	47	23.4
Severe	13	6.5
Antibiotics for secondary infection	11	5.5
Total	100	49.8

All patients were men 17 to 45 years old who met the physical standards for active duty in the Navy.

Four paired sera from patients admitted to sick bay were tested at Preventive Medicine Unit No. 2 Norfolk, Va. and two of the sera showed marked reactions in the specific hemagglutination

inhibition test to the antigen of Earle's isolate A/Japan/70, 57 the Asian influenza virus.

Sera were also tested against influenza types A/PR8/34, A/FM1/50 (A/Denver/57) B/GI/54 and B/Isc/10. These sera showed no significant rise in titer. This result is considered definite evidence that the epidemic was the Asian type of influenza.

### SYMPTOMS

In the majority of cases the disease began either with coryza and a gradually increasing headache, or suddenly with a shivering chill. All cases developed a significant fever, 102°F or more at some time during the disease. Table 2 presents a summary of the symptoms that were reported by the patients. As most pronounced migratory arthralgia without overt arthritis was common,

TABLE 2. Symptoms, signs and severity of Asian influenza in patients placed in sick bay during first, middle and last periods of epidemic.

Symptom, sign or severity	Per cent of total group of 71 cases	Per cent of first 25 cases	Per cent of middle 21 cases	Per cent of last 25 cases
Headache	39	32	33	48
Arthralgia	34	70	33	48
Myalgia	49	56	48	44
Chills	49	48	38	60
Cough	37	36	48	28
Diarrhea	11	12	10	12
Asthenia	13	12	24	4
Sore throat	10	20	5	4
Rales right lung base	34	16	38	48
Rales left lung base	17	8	29	16
Mild infection	66	68	76	56
Severe infection	18	16	14	24
Antibiotics for Secondary infection	15	16	10	20

as was myalgia, which caused considerable discomfort. Some of the patients complained often of a severe backache at the base of the back. The cough tended to follow the rise in temperature by about 24 hours, and was associated with fine rales in less than half the cases. Asthenia, so common in pandemic influenza,<sup>2</sup> was of little importance in this epidemic. Rales tended to be found most often at the right lung base, and usually developed during

the second or third day of the infection Sore throat coupled with an "injected" pharynx occurred frequently

### STATISTICS

In this paper the number in a category was compared to the expected values predicted from the behavior of the total epidemic and tested by the chi square technique The expected value was derived as follows If A was the value of a certain category in group n and B the value of the same category in a larger group z, the expected value of B was equivalent to B times the total number of cases in group a divided by the total number of cases in group z This expected value was then compared to A by the chi square technique Yates' correction was used where the number of cases was less than 5 and/or where the degrees of freedom were less than 3 For a difference to have been statistically significant in this study it must have differed to the 1 per cent level of confidence

### PROGRESSION AND SEVERITY OF SYMPTOMS

To test whether the severity of the disease changed during the epidemic the first 25 cases admitted between 1 and 5 July the middle 21 cases and the last 25 cases admitted after 6 July are compared in table 2 Testing each category of these three groups against the corresponding value as predicted from the total group showed no significant variation in the symptoms or severity during the course of the epidemic The average initial temperature (101.9 F) and the average time spent on the sick list (2.9 days) also showed no significant variation between the three groups or from the total group

Using the grades of severity outlined above and comparing the average maximum temperature for each group to that for the total epidemic there was no significant relationship between severity of influenza and maximum temperature

### EFFECT OF BERTHING AND WORKING CONDITIONS

During the epidemic the *Valcour* had a total complement of 13 officers, 7 chief petty officers, and 181 enlisted men The men were classified into divisions by occupational and berthing assignments (fig 1) After 2 July the "Flag" compartment was used as an isolation ward and the men were transferred to bunks in the V and \ division compartment The divisions followed standard Navy designators The men who transferred from the U S S *Greenwich Bay* were put with the V and \ division The M division contained the ship's engineers All of these men slept in the same compartment and all but the shipfitters worked in close association in the engine rooms First division personnel worked about the deck and were less confined during the working day Personnel of divisions V, \, O, N, and F the stewards, the

chiefs, and the officer over in smaller, rooms had more ordinary jobs, and were distributed about the ship. Each compartment had a separate air conditioning system.

Figure 1. Berthing diagram of the U S S Valcour by divisions.

Statistically there was no significant difference between the number of men infected from each division and the number that would be expected as predicted from the total group (table 3). The distribution of severity of the infection in each division of the ship as compared to that expected from the total number of that severity reduced proportionately, also was not significant by the chi square test (table 4).

TABLE 3. Incidence of influenza by divisions.

Division	Number of men	Number infected	Number expected from total
M	58	22	20.5
S	30	7	10.6
First	31	14	11
O, N, F, stewards	43	17	15
V, X, transfers	19	7	7
chiefs, officers	20	4	7
Total	201	71	71

Calculated as follows:  $201 \times 71 = 58 \times 20.5$

TABLE 4 *Serotype features by division*

Division	Total number infected	Number with mild infection	Number expected to have mild infection	Number with severe infection	Number expected to have severe infection	Number exposed to an "boost" for secondary infection	Number expected to require antibiotic for secondary infection

Total	71	44	47	13	13	11	11

\*Calculated by using  $\chi^2$  test,  $p < .05$ 

## INCIDENCE BY DAYS

Figure 2 indicates the number of men of each group who were disabled each day. The striking onset in M division on 4 July correlated with the long watch and the rapid change in temperature while traversing the Suez Canal. The men repeatedly went from the hot engine room to the cooler deck to see the canal. While on deck they stripped to get a sun tan and were chilled by the deceptively cool breeze. The ease of droplet spread and greater virus stability in the hot moist engine room might also have explained this sudden onset.<sup>3</sup>

## CONTROL

Because of the cramped shipboard berthing quarters and the nature of the ship's air conditioning system it was impossible to isolate patients at less than the division level. As soon as cases were detected they were isolated in a separate compartment but with a "head" common to the rest of the crew. This appeared to have little effect on the spread of the disease. The incubation period seemed to be about 48 hours during which time the only symptom was a nonspecific coryza. Using the chi square test neither the attack rate nor the daily incidence rate of those who were not exposed at Aden differ significantly from the rates of those who were exposed in Aden.

## COMPARISON WITH THE 1918-1919 PANDEMIC

The epidemic of influenza observed by Opie and associates<sup>4</sup> in 1918 at Camp Pike occurred in a relatively isolated military population much like that involved in the present study. The 100 consecutive cases reported from the height of the 1918 epidemic

Figure 2 Daily incidence of epidemic by divisions

were similar to the 71 observed in 1957, with minor exceptions. Epistaxis, which was not seen in the 1957 series, occurred 12 times in the 1918 group. On the other hand asthenia and diarrhea were significantly more prominent in the current series.

Dudley<sup>2</sup> reported 368 cases seen on the hospital ship H. M. S. *Agadir* in the late fall and winter of 1918 to 1919. The pandemic reportedly was more severe as it progressed and, in addition, the series seen on a hospital ship presumably would have been weighted toward the more severe cases. About 6 per cent of the 368 patients died of pneumonia, whereas there were no deaths in the current series. There also was a longer duration of fever in uncomplicated cases of the *Agadir* group. This is shown in figure 3, in which the duration of fever is plotted against that for corresponding groups in the other two series. Fevers recurring after 48 hours of normal temperature were not included.

It can be seen from table 5 that the range of severity and complicating pneumonitis in patients seen in 1957 was similar to that in the 1918 to 1919 reports, with the exception that no deaths occurred.

Figure 3 Comparison of duration of fever in uncomplicated influenza in the 1957 and the 1918-1919 epidemics.

TABLE 5 Comparison of severity of 1957 epidemic and 1918-1919 pandemic

Severity	Valcour (1957) 71 cases		Opic et al. <sup>4</sup> (1918) 100 cases		Dudley (1919) 368 cases	
	Number	Percent	Number	Percent	Number	Percent
Uncomplicated	47	66	64	64	285	77
Cases with pulmonary signs	24	34	36	36		
Pneumonias with fever	11	15	15	15	83	23

### COMMENTS

It appears that either repeated chilling and heating and loss of sleep or the working conditions of the engineering division could make the infection spread more rapidly. There was no evidence that the infection which appeared more quickly in this way was any more severe or led to more sequelae. The officers, who were better isolated, suffered a specific attack rate not significantly different from the crew. Face masks were not used. The disease could be controlled adequately with symptomatic therapy and antibiotics were used only when pneumonitis appeared as a complication following partial recovery. The predominance of pulmonary cases in the right base as compared to those in the left base was not significant.

The 1957 epidemic here reported, when compared to two studies on similar populations during the 1918-1919 pandemic showed striking similarities in symptomatology and severity. The only important differences lay in the prevention of secondary pneumonia with antibiotics and in the fact that no deaths occurred. The deaths in the Lyadir 1918 to 1919 series were caused by pneumonia.

In the course of the epidemic all three of the Medical Department representatives on the ship became infected. This relatively mild infection disabled a considerable portion of the ship's company, if it had been more virulent it could have disabled the entire ship and rendered it ineffective as a fighting unit.

### SUMMARY

An epidemic of Asian influenza aboard a relatively isolated naval ship disabled 35.3 per cent of the ship's company for varying lengths of time over a period of 14 days. The natural history of the epidemic in this closed environment was examined statistically. There was no evidence that the epidemic changed progressively in severity or that the amount and type of physical labor affected its severity or overall incidence. There was evidence that either repeated chilling or confinement in a warm, moist environment could cause the infection to spread more rapidly, but the infection thus spread was not more virulent. A comparison with two studies of the 1918-1919 pandemic in similar military populations showed no significant differences in severity. Control measures were not effective and the infection proved to be a grave military hazard.

---

**ACKNOWLEDGMENT** The author wishes to thank Lieutenant R. D. Alexander, MSC USN and Lieutenant (jg) W. R. Sanborn, MSC USN of Preventive Medicine Unit No. 2 Naval Operations Base Norfolk Va. for their help in identifying the virus.

# USE OF THE BATROW NEUROMUSCULAR STIMULATOR FOR INDUCING RESPIRATION IN GB POISONED ANIMALS

FRED W OBERST *Ph.D.*  
WILTON A CHRISTENSEN *B.A.*  
JAMES W CROOK *B.S.*  
PAUL CRESTHULL *B.S.*

SEVERAL methods of artificial respiration have been found effective in resuscitating GB\* poisoned animals. Oberst and associates<sup>1</sup> found no appreciable difference between the effectiveness of the mask and the tracheal tube methods of artificial respiration in resuscitating dogs exposed by inhalation to 3 to 40 lethal doses of GB vapor.

In recent years several electric stimulators have appeared on the market each having characteristics supposedly useful in inducing artificial respiration. Sarnoff, Herdenbergh, and Whittenberger<sup>2</sup> described an apparatus\*\* capable of producing artificial respiration by electric stimulation of one or both phrenic nerves. The stimulus is a series of impulses the voltage of which rises and falls in such a way as to produce effective diaphragmatic contraction and relaxation. Sarnoff, Herdenbergh and Whittenberger<sup>2</sup> reported that effective respiratory activity could be induced, and that the technique was capable of maintaining normal partial pressures of oxygen and carbon dioxide in the arterial blood of experimental animals and in man, in the absence of spontaneous respiration. In unpublished experiments carried out by Wills and his associates<sup>3</sup> this type of stimulator did not produce effective artificial respiration in dogs poisoned with lethal doses of GB.

The Batrow neuromuscular stimulator\*\*\* is another type of electric stimulator that generates a current effective in producing muscular contraction. Essentially it consists of a generator capable of delivering from 17 to 20 microamperes at 25,000 to 60,000 volts in a series of highly damped 7 microsecond oscillations.

From Toxicology Division, Chemical Warfare Laboratories, U. S. Army Chemical Center, Md.

\*Nerve gas with the chemical name of diisopropylmethylphosphonofluoridate.

The Sarnoff Electrophrenic Stimulator is manufactured by Sanborn Co., Cambridge, Mass.

Made by Batrow Laboratories, Branford, Conn.

This apparatus has been proposed for treatment of certain types of neuromuscular dysfunctions. The manufacturer also has suggested its use for resuscitating drowning and smoke victims by stimulation of the diaphragmatic muscles.

In our studies the Bntrow neuromuscular stimulator was tested for its effectiveness in resuscitating dogs and Rhesus monkeys poisoned by inhalation of lethal concentrations of GB vapor.

### METHODS AND MATERIALS

Six dogs, each weighing, approximately 10 kg, were shaved in the abdominothoracic area where the stimulating electrode (applicator) was to be placed, and an area on the back also was shaved for placing the return plate (ground). To ensure good electric contact, both the stimulating electrode and the return plate were wrapped in a cloth dampened with tap water. A tracheal tube with a Sanders cuff was inserted into each dog. The tube was connected by a 2 way valve and short rubber tubing to a small Collins gasometer equipped with a pen and kymograph for recording air movements. For dogs, a surge setting of 5, a pulse setting of 3, and an intensity setting of 8 on the apparatus appeared to give the best physical response of the chest wall and diaphragm, but other settings were also tried.

Rhesus monkeys weighing from 3 to 6 kg were not shaved for placement of the electrodes, but the instrument settings used were similar to those for the dog.

In preliminary tests, 3 of the 6 dogs were used to test the action of the stimulator on respiration at various instrument settings and positions of the stimulating electrode. These animals also served as controls for dogs exposed by inhalation to GB vapor. One of the control dogs received Nembutal (brand of pentobarbital sodium), one, curare, and another, a combination of those drugs. All GB exposed dogs and monkeys, except one, received atropine (5 mg per kg of body weight for the dog, and 2 mg per kg for the monkey) intramuscularly one half to three minutes after the one minute inhalation exposure. One monkey did not receive atropine.

### RESULTS

**Dogs.** Alterations in the respiratory rate and volume due to electric stimulation were studied on the nembutalized dog. Subjective observations on this animal indicated that the tidal volume was not altered appreciably, however, at increased intensities the rate of respiration was synchronized with the rate setting on the instrument. Another animal received sufficient curare to inhibit respiration completely. The electrostimulator caused marked, spastic like chest movements but did not move an appreciable amount of air as observed by the recordings on the kymograph.

The dog showed marked signs of anoxia and was dead 5 to 6 minutes after the curaro injection

On the basis of the foregoing results a third animal was first given Nembutal, and then curaro was administered intravenously in dosages which lowered the respiratory rate and volume. Application of electrostimulation did not increase the tidal volume but the frequency of respiratory activity could be controlled by the pulse setting on the instrument. The same results were noted after additional administration of curare which caused a further lowering of respiratory rate and volume. When sufficient curaro was administered to inhibit respiration completely, the electrostimulator caused muscular contractions that appeared spastic in nature, but little or no respiratory ventilation occurred. The animal became hypoxic and would have died under these conditions of treatment. When death was imminent, the operator disconnected the tracheal tube from the spirometer and connected it to a mechanical resuscitator. In a short time the color of the tongue and mouth changed from dark blue to pink, indicating effective pulmonary ventilation. After a few minutes, the method of respiration was changed to the electrostimulator, and the same condition of anoxia occurred as before and the animal was again on the verge of death. Once more, mechanical respiration was effective in relieving the animal's anoxic condition.

Three dogs were exposed to GB vapor, equivalent to approximately 3 LCt50's\* (187 mg min/m<sup>3</sup>). After the exposure they were treated with atropine followed immediately by electrostimulation. In the first animal atropine was administered and electrostimulation was initiated three minutes after exposure. Spontaneous respiration had ceased by this time. Electrostimulation caused vigorous muscular action synchronous with the rate set on the instrument but did not move an appreciable amount of air as recorded on the kymograph. The dog did not show signs of spontaneous respiration and was dead within three to four minutes after resuscitation was initiated. In previous experiments on dogs similarly poisoned with GB a mechanical respirator saved the animals. Because treatment in the foregoing animal was not started until respiration had ceased the experiment was repeated on a second animal except that treatment was started one-half minute after the exposure and while spontaneous respiration was still in effect. The outcome was as unsuccessful as before. When spontaneous respiration ceased the electrostimulation did not produce adequate respiration. In the third dog treated one-half minute after exposure to GB vapor, electrostimulation failed to maintain adequate ventilation. When anoxia became severe and the animal appeared to be dying the tracheal tube leading to the

LCt50—the prod ct of apor conc and time d time of exposure resulting in 50 per cent lethality —Editor

spirometer was disconnected. One of us ventilated the blowing through the tube into the dog's lungs. Within 10 minutes color improved, and within another two minutes respiration became spontaneous. There is no question but that the animal could have died under electrostimulation.

**Rhesus Monkeys.** The results in five rhesus monkeys are shown in table 1. All except one received atropine. Electrostimulation was started at approximately the same time as the atropine administration. The results show that the electrostimulation was not effective. The only monkey that survived never stopped breathing and received atropine early, one half minute after the exposure.

TABLE 1. Evaluation of the Batrow neuromuscular stimulus on five rhesus monkeys poisoned with GB.

Subject	Time for appearance of toxic signs (in minutes)		Time of atropine administration (in minutes)	Initiation of electrostimulation (in minutes)	Approximate time of death (in minutes)
	Tremors	Convulsions			
1	0.5		None	0.5	6
2		None	0.5	0.5	Survived
3		1.7	1.7	2.0	10
4		1.5	1.0	0.5	12
5	0.2		0.3	0.5	5

The times recorded in the table commence at the end of the 1 minute exposure.  
*Cardiac arrest.*

There is no doubt from past experience that all the atropinized animals would have survived, if effective artificial respiration had been employed. In the animal receiving no atropine, life could have been supported for a considerable time by means of a good mechanical respirator.

#### DISCUSSION

While the Batrow neuromuscular stimulator may be very useful for stimulation of muscles, it is not an effective device for artificial respiration. It did not produce the necessary alternations between the inspiratory and expiratory muscles which are essential for adequate ventilation. The inspiratory muscle effects that resulted from stimulation with the applicator placed over the diaphragm were probably counteracted by the simultaneous stimulation of the expiratory muscles. When the intensity was set high enough to give strong contractions, contractions were of a spastic nature. Regardless of whether curare or GB poisoning caused the neuromuscular block, as studied here, the resuscitator was unable to overcome the block.

## SUMMARY

The Batrow neuromuscular stimulator in conjunction with atropine therapy was evaluated as an electric resuscitator in dogs and monkeys poisoned with lethal amounts of GB vapor. Two curarized dogs also were used in these experiments. The stimulator was ineffective in resuscitating these animals. It caused spastic like contraction of the respiratory muscles but did not cause respiratory exchange adequate for survival.

## CHRONIC FEARFULNESS

"Everyone recognizes that there are diseases of the body and diseases of the mind. Many thoughtful people believe that there are also diseases of the spirit, important in themselves and capable of producing pronounced secondary disorders of body and mind. Spiritual disorders include pride, jealousy, greed, self-pity, resentment, self-indulgence, and chronic fearfulness. As an example of the latter I may tell you of an eminent surgeon who had a patient with a dangerous and painful illness requiring an operation involving serious risk. She showed great courage and endurance in contrast to her husband who was a worrying little man, fussy over trifles and consumed by fearfulness. Many times during those difficult weeks he telephoned or visited the surgeon about trivialities. Eventually the patient reached a stage of convalescence. One day, again by special appointment the husband came to the surgeon and asked, 'Mr. Jones, do you think I ought to get a bath chair?' The harassed surgeon answered crisply, 'You can if you like, but I don't think she's strong enough yet to push you around.'

# INFERIOR DEEP CERVICAL LYMPH NODE BIOPSY

JACK R. JAY, Major, USAF

THOMAS H. HEFFERTY, Lieutenant Colonel, USAF

**I**N 1949 Daniels<sup>1</sup> described a method of biopsy useful in diagnosing certain intrathoracic diseases. He reported five cases. Since then several large series of cases substantiating the usefulness of the procedure have been reported.<sup>2-4</sup> As a result of these reports this operation gained wide acceptance until it became apparent that it produced large numbers of false negative results. Because of this, the procedure has now fallen into some disrepute. The purpose of this article is to discuss some of the causes for the inaccurate results, and to emphasize some important points designed to improve the diagnostic accuracy of this operation.

Names such as supraclavicular lymph node biopsy, retroclavicular lymph node biopsy, and prescalene lymph node biopsy have been applied to this procedure. It is thought, however, that none of these adequately describe the location of the lymph nodes to be excised. The lymph nodes alluded to lie on the anterior scalene muscle and around the junction of the subclavian and internal jugular veins. These nodes have always been called the inferior deep cervical lymph nodes,<sup>5,6</sup> and although the other titles may have brevity to commend them, this advantage is lost by their clouded anatomic connotation. Because of the use of the above vague and varied terminology, the exact material to be excised has frequently been overlooked. Often, as illustrated in our series of 74 consecutive cases, no lymph nodes were found in the specimen (table 1). Twenty five and sixteenth parts per cent contained no material of value in diagnosing spread of intrathoracic disease. Most of the biopsies in this series were performed by junior house officers. A 2- to 4 cm incision was made, and the entire operation took about one half hour to complete.

Emphasis must be placed on the fact that many different surgeons, primarily first- and second year residents, performed the

surgical procedure on this group of patients. The method of biopsy used was that described by Daniels.

The failures, of course, cannot be ascribed to lack of clear description of the operative technique inasmuch as this has been adequately accomplished by several writers. Rather, we believe that the failure lies primarily in the fact that this procedure is thought of as a simple, 10 minute operation without mortality or morbidity. Accordingly, the most junior member of the sur-

sical staff has been assigned to delve among the great vessels at the base of the neck and extract the fat pad lying on the anterior scalene muscle, hoping thereby to remove some or all of the inferior deep cervical lymph nodes. This, as is amply illustrated by our series of patients does not produce the desired diagnostic results. In our opinion it requires a 5 to 6 cm incision for adequate exposure, and about one hour of a trained surgeon's time to safely extract the elusive deep lying lymph nodes from their hiding places about the subclavian and internal jugular veins. The surgeon, in addition, must be interested in and aware of the problems inherent in this procedure. Obviously enlarged and palpable lymph nodes at the base of the neck in the subclavian triangle present no major surgical problems, and the incidence of positive results under these circumstances is very high indeed. It is the occult, small, impalpable node that escapes our eye and finger, and for which we must diligently search if we are to improve our diagnostic ability and thereby prevent needless surgery of benign and/or inoperable malignant lesions. In our series only 10.3 per cent of occult nodes were positive.

Selection of the side of operation also plays an important role to increase diagnostic accuracy. As emphasized by Harken and associates<sup>7</sup> and Connor,<sup>8</sup> the description of the lymphatic drainage of the lung by Rouviere,<sup>9</sup> indicates that the right lung and the lower two thirds of the left lung drain eventually to the right inferior deep cervical and mediastinal lymph nodes, whereas the upper one third of the left lung only drains to the left side of the mediastinum and neck. This finding, naturally, locates the side of incision. However the finding of negative lymph nodes in an adequate, right, deep cervical lymph node biopsy, performed for a lesion in the lower two thirds of the left lung, probably should indicate the need for biopsy on the opposite side. One patient in the series reported had a left lower lobe lesion. A left, inferior deep cervical lymph node biopsy was performed with positive results.

Cervicomedastinal biopsy, as advocated by Harken and associates, has not as yet won general approval, however, it may eventually be the procedure of choice. Connor reported an incidence of 31 per cent positive inferior deep cervical lymph node without mediastinal biopsy in cases with a proven diagnosis of carcinoma of the lung. This latter figure, when examined, reveals that it includes six cases of palpable nodes and thus, if it is to be compared with that of Harken and associates (39.8 per cent), must exclude those cases, giving a true incidence of 26 per cent positive biopsies. This may represent a significant difference between these two procedures. Those figures reported by Shefts, Terrill, and Swindell<sup>4</sup> do not state if nodes were palpable and thus cannot be readily compared. However, it is interesting to note that their incidence of positive biopsies was lower than that

reported by Harken and associates. Even with the high incidence of positive biopsies using the method advocated by Harken and associates the increased discomfort the patient experiences, plus the possibility of damage to the great vessels, makes one slow to accept such a procedure.

Finally routine inferior deep cervical lymph node biopsy is not indicated in all pulmonary lesions. Only those lesions showing a high incidence of positive lymph nodes in the operative specimen should be included.

These collected cases (listed in table 2) indicate there is little value in biopsy when a mediastinal tumor carcinoma of the esophagus or intrathoracic metastasis is suspected. In addition a hilar or pulmonary lesion suspected as being tuberculous seems to give few positive results. Table 3 also indicates that there is a rather wide range of positive results reported from different institutions and that therefore defects in technique or ability to find pathologic nodes must exist.

The figures shown in table 3 indicate the per cent of the final diagnosis (established by all methods) that was made by inferior deep cervical lymph node biopsy. Some of the authors quoted this percentage figure on only one diagnosis and consequently the total cases indicated are those relative to that diagnosis alone.<sup>4, 7, 10</sup>

It is to be noted that a number of patients reported on by Carstensen, Norvitt and Odolberg<sup>10</sup> had clinically palpable nodes, and Shefts, Terrill and Swindell did not indicate if the nodes found in the patients were palpable preoperatively. This of course may account for the high range of diagnostic accuracy reported in their studies. The problem most commonly encountered is that of a pulmonary or mediastinal lesion without palpable inferior deep cervical lymphadenopathy, and this therefore should be the test for procedure accuracy.

#### SUMMARY

In a series of 74 consecutive cases of inferior deep cervical lymph node biopsy it is emphasized that this is not a minor surgical procedure to be delegated to the most junior member of the surgical staff. In this series of cases the operation was performed by different physicians, ranging from intern to fully trained surgeon. Most of the procedures were performed by first and second year residents. The selection of the side of operation based on the lymphatic drainage of the lungs is an important facet in increasing the diagnostic accuracy of the procedure. Not all pulmonary lesions yield a high incidence of positive inferior cervical lymph node biopsy. The most important criterion in evaluating this procedure is its incidence of positive lymph

TABLE 2 Summary of diagnoses in collected series of inferior deep cervical lymph node biopsy

# FORENSIC PSYCHIATRY IN THE ARMED FORCES

HARRY ROSENBERG, M.D.

**D**URING the past few years there has been an increasing interest in the problems of forensic psychiatry. Recent books by Zilboorg,<sup>1</sup> Overholser,<sup>2</sup> Biggs,<sup>3</sup> and Weisbaden<sup>4</sup> not only pointed up the old problems, such as the basic relationship between psychiatry and law, but raised many new questions. Although these problems have been explored extensively in civilian courts, little attention has been paid to them as they exist in the armed services.

The psychiatrist entering military life may wonder what is the military law in cases where insanity is a defense, and also what restrictions there will be, if any, on his psychiatric formulations based on his training and life experiences and evaluation of the patient, if asked to testify in a military court. It was my experience while in military service that most psychiatrists who first came into service believed that military life in itself was almost synonymous with some restrictions on their professional thinking and expression. This of course is not so, in fact, a careful review of recent cases shows that military courts are increasingly interested in psychiatric testimony and want more rather than less information.

This article will highlight four recent decisions, all of which have the common feature of emphasizing the importance of psychiatric testimony in the military court and the belief of the judges on the Court of Military Appeals, the highest legal tribunal in the military, that meaningful, dynamic psychiatry has an important place in the military courtroom.

The basic law of mental responsibility in the military is found in the *Manual for Courts-Martial*, and is as follows:

---

From Kings County Psychiatric Hospital Unit, Kings County Hospital Center, Brooklyn, N. Y. Dr. Rosenberg is now at 57 Flower Road, Valley Stream, N. Y.

Presented as part of a paper entitled *Current Problems and Progress in Forensic Psychiatry and The Law* at the panel on Military Medicine at the annual meeting of the American Psychiatric Association, April 1946.

A person is not mentally responsible in a criminal sense for an offense unless he was at the time so far free from mental defect disease or derangement as to be able concerning the particular act charged both to distinguish right from wrong and to adhere to the right.<sup>3</sup> The phrase "mental defect disease or derangement" comprehends those irrational states of mind that are the result of deterioration destruction or malfunction of the mental as distinguished from the moral faculties.

To constitute lack of mental responsibility the impairment must not only be the result of mental defect disease or derangement but must also completely deprive the accused of his ability to distinguish right from wrong or to adhere to the right as to the act charged. Thus a mere defect of character will power or behavior as manifested by one or more offenses ungovernable passion or otherwise does not necessarily indicate insanity even though it may demonstrate a diminution or impairment in ability to adhere to the right in respect to the act charged. Similarly mental disease as such does not always amount to mental irresponsibility. For example if a person commits an assault under psychotic delusion with a view to redressing or revenging some supposed injury to his reputation he is nevertheless mentally responsible if he knew at the time that the act was contrary to law and if he was not acting under an irresistible impulse. On the other hand an accused is not responsible for a particular homicide if as a result of mental disease he had an insane delusion that another person was in the act of attempting to kill him and he thereupon killed the supposed attacker under the delusion that it was necessary to kill the deceased to preserve his own life.<sup>4</sup>

Irresistible impulse as a defense also is permissible. The Durham rule has not been accepted. This rule which the Court of Appeals District of Columbia unanimously adopted to replace the M'Naghten test and the irresistible impulse test for mental responsibility was: "It is simply that an accused is not criminally responsible if his unlawful act was the product of mental disease or mental defect."<sup>5</sup> The court correctly indicated that the fundamental objection to the right/wrong test was not that criminal irresponsibility was made to rest upon an inadequate invalid or indeterminable symptom or manifestation, but that it is made to rest upon any particular symptom.

In attempting to define insanity in terms of a symptom the courts have assumed an impossible role not merely one for which they have no special competence. In this field of law as in others the fact finder should be free to consider all information advanced by relevant scientific disciplines.<sup>6</sup>

In two cases *United States versus Smith*<sup>7</sup> and *United States versus Kunak*<sup>8</sup> the judges, in particular Judge Paul W. Brosman and Judge George W. Latimer did refer to this new rule, but

time of the offense " He had considered the accused " an anxiety neurosis but as the picture began to unfold, it is a long standing pattern and continual struggle with these various episodes and the final diagnosis, as I recall, was emotional instability reaction with barbiturate addiction "

Since the diagnosis of emotional instability is a character disorder and not a recognized military mental disorder, the defense of irresistible impulse was not allowed

Following her conviction Mrs Smith was examined by expert civilian consultants one in psychiatry and one in clinical psychology They were Dr Alexander Simon and Dr Douglas M Kelley These consultants concluded that at the time of the offense the accused was not able to distinguish right from wrong or to adhere to the right. This led Chief Judge Quinn, who presided in the case, to state

The medical officers who have examined Mrs Smith and whose names will be signed to these findings function in a somewhat differently structured medico-legal context than their civilian colleagues who have also examined the accused By this it is inferred that as to what findings he may make by the established body of medico-legal policy and precedent now codified in part in TM 8-240 It is the impression of the undersigned that in a civilian jurisdiction a much more liberal interpretation of issues of mental responsibility in crimes of violence is frequently observed These statements are made in an attempt to explain some of the differences of opinion as to the accused's responsibility expressed by military and civilian psychiatrists

In the case of the United States versus Kunak the defense was entirely that of insanity Kunak was charged with the murder of 2nd Lt Harold B Williamson He had been seen approaching the table where Lt Williamson was seated He then executed a right face, lifted a carbine and shot Lt Williamson Previous history revealed that Kunak had a half brother and a sister in mental institutions As a civilian Kunak had jumped from a 75 foot bridge, and on occasion had attempted to balance himself on his head while riding a motorcycle at a high rate of speed

There were at least two military sanity boards, one before and one after trial They both found the defendant sane at the time of the alleged offense The second sanity board was held at Fitzsimons Army Hospital in Denver, Colorado The findings of this board were to the effect that while " the accused was suffering from emotional instability, he was sane at the time the offense was committed, at the time of trial, and at the time he

was examined.<sup>22</sup> The conviction was upheld, but before the case went to the Court of Military Appeals the parties entered into a stipulation that further action should be suspended in order that Dr Manfred S. Guttmacher be allowed to examine the accused. His report as reported in the Court of Military Appeals' decision,<sup>23</sup> was as follows:

In this Examiner's opinion the patient is a paranoid schizophrenic. It is his definite opinion that this patient was not a legally responsible agent at the time of his offense and that he is insane now. It is his belief that the patient was suffering from a psychotic irresistible impulse at the time of the crime and that he did not have a full appreciation of the wrongfulness of his acts.

In reviewing this whole situation longitudinally, it seems difficult to understand how a psychiatrist could come to any other conclusion in this case. He does not impress the Examiner as one of those borderline psychotics but rather as a flagrant one.<sup>24</sup>

In this case the restrictive effect of TM 8-240 were also discussed, although it was more definitely criticized in the Covert case.<sup>25</sup> In the Funk case Judge Quinn noted that this type of technical manual "circumscribes the testimonial freedom" of the military expert witnesses.

In *United States versus Dunnahoo*,<sup>26</sup> the problem of character disorders as related to the capacity to premeditate was a prominent issue. The charge was homicide. Dunnahoo, a soldier stationed in Germany, had spent the greater part of one July afternoon in 1954 "in guesthouses near the Schlossheim Forest, Munich, Germany, where he reputedly consumed several beers. Sometime during that afternoon he entered the Forest and his asserted reason was that he intended to locate a prostitute. However, before finding a woman, he changed his mind and decided to return to the city. It was on his return journey that he first saw the decedent," a German national who lived with his parents in the immediate vicinity. After pausing to talk briefly with the boy, the accused continued on his way, "but observed that the boy followed." Then, according to the accused, the boy "started grinning like he was making fun of me or something." This angered the accused, and he struck the boy, knocking him to the ground. "The boy tried to escape but was again caught. The accused later explained, 'I might as well hit him a couple of more times. I would get just as much punishment as if I only hit him once.' At this point and without reason or excuse the accused killed the boy by means of a pocket knife" and mutilated the body.<sup>27</sup>

When apprehended, the accused signed two pre-trial statements. "The first statement indicated that he had killed the

victim under the delusion that the object he was stabbing was, in fact a bear and that the body was mutilated in an attempt to prevent the meat from acquiring a rank' or odorous taste."

Dunnahoo was diagnosed as a character and behavior disorder—in particular aggressive reaction. He was tried and found guilty and sentenced to death. When the case was argued before the Court of Military Appeals the defense maintained that although the accused was legally sane, a character disorder should be considered as to the capacity of the accused to premeditate in regard to his alleged offense, and that in this case it had not been considered. The court agreed with him.

From the psychiatric point of view this was important because it meant that now the courts would have to enlarge their inquiry in cases of this type from just the old "able to distinguish right from wrong" rule (M'Naghten rule) to an inquiry into the patient's mental status at the time the act was committed. As the court noted

We know of no good reason why military law should not embrace principles which keep the courts martial abreast of medical science particularly when the military medical service advances compelling reasons for their adoption. Certainly the state of mind with which a person commits a criminal act is material in determining whether he should be punished therefor and if so how severely."

The court continued

Expert witnesses are seldom asked to express an opinion except on legal insanity and we believe the cavalier treatment accorded the subject of diminution of capacity which we find in many records is not in keeping with the consideration given to the subject of insanity by the military services. We conclude that character disorders as defined in the military medical manuals and regulations should be considered in measuring a person's mental ability to premeditate."

In the final case to be presented United States versus Covert<sup>14</sup> a number of different points were emphasized, all tending to free the psychiatrist from restrictive regulations. The accused had killed her husband an acknowledged drunkard. He had been in frequent financial trouble and had spent most of his wife's accumulated savings of more than \$5,000.00 before re-entering military service in 1946.

They were stationed in England when the wife received word that she was about to inherit a sizable sum of money. She wanted to save it but her husband wanted to buy a car and tour the continent. She thought that her husband was more and more like her father who had been resentful of the fact that she had not been

a boy and who had gone so far as to try to get out of a window on one occasion and on another to climb her

Mrs. Covert became depressed and sought medical attention at the Air Force Hospital. She was seen by a psychiatrist. He was impressed by her agitation and depression and considered immediate hospitalization but decided against it at that time in view of the limited medical facilities and what he deemed the absence of urgency. He gave her another appointment to return the next day.

The accused returned home and was described by a neighbor as being in good spirits. She did not have any arguments with her husband that evening but after he retired she killed him while he slept with an ax. Later she could not offer any reason for the act. She removed her flannel pajamas which, being covered with blood, she placed in a washtub. She then covered her dead husband, took a heavy dose of drugs, and went to sleep in the same bed with the body of her husband.

The next day she appeared for her 2 p.m. appointment with the psychiatrist. He asked about the state of her health and she commented that it was "not so good." Then with no sort of preface she stated in an unemotional and dull monotone "I killed Eddie last night."

The psychiatrist considered that she had been psychotically depressed and was not sane at the time of the alleged offense. Further, she had told him (she was an unreconstructed Southerner) that even the presence of General Sherman would not have prevented her from killing her spouse. Three other psychiatrists who examined her believed that she was seriously ill, but sane.

Mrs. Covert was convicted. After the trial two of the psychiatrists submitted voluntary statements to the effect that they had believed they were bound by provisions of TM 8-240, which restricted their professional opinions. When the defense argued the case before the Court of Military Appeals it was pointed out that the psychiatrists had too literally applied the "police man at the elbow test"\* when the question of irresistible impulse had been raised. The Court of Military Appeals agreed that this had in effect been the case. They reversed the conviction and ordered a new trial.

Chief Judge Quinn stated:

In the *Smith* case, I noted that the military medical experts were obviously testifying to what they believed the service manuals required "to the exclusion of their individual beliefs." This case confirms my

fear that use of the technical manuals on psychiatry are depriving the accused of the right to unbiased and truly professional opinions from military psychiatrists

I am glad Judge Brosman has recognized the improper influence of the technical manual in this case and I concur with him in setting aside the conviction and ordering a rehearing. At the same time I cannot refrain from expressing regret that he has not joined me in a general condemnation of the present use of the service manuals as a restrictive influence on the testimonial freedom of the service doctors.

In summary what has been the over-all effect of these cases in military law and why are they so important to the service psychiatrist? It is my opinion that the psychiatrist has been freed from restrictive regulations and has been given the freedom to testify freely and fully and in his own dynamic language as to his findings. Furthermore, it behooves the military courts to listen to his findings if they are to function properly and intelligently as the judges on the Court of Military Appeals have stated over and over again. Meaningful psychiatry can now enter the military courtroom.

# A TECHNIC FOR MILITARY DELINQUENCY MANAGEMENT

## II Methods and Results\*

BRUCE L. BLSHARD *Lieutenant Colonel MC USA*  
ARNOLD W. DAHLGREN *Major MPC USAR*

THE WORKING OUT and establishment of a program designed to avert difficulties previously encountered in a post stockade and in prisons at large and to retain control of the situation in the hands of the administration requires mutual respect, understanding, support, and co operation from the post commander and his staff, the confinement officer and his staff, and the psychiatrist and his staff.<sup>1</sup> Without this, no such program could be successful. The program described appears to involve the following factors:

### COMMAND RESPONSIBILITIES

When the Rehabilitation Company was first established, nearly 1 of its members promptly went AWOL (absent without leave). This was blamed upon faulty screening techniques, but whatever the reason, the AWOL rate of this group (the mass of whom are confined because of AWOL) has, since that time, been generally lower than that of the post at large. Periods of many months have passed without an AWOL. A three day home parole has been given both Christmases and only one prisoner has violated it. A program like this requires, then, one undeniable consideration. The command must be interested enough to tolerate some early growing pains and must recognize that such incidents are only outstanding examples of the renowned tendency of prisoners to test the limits—to see how far they can go. Everyone must be willing to take a chance and to recognize that some problem will arise. To operate the stockade in such a way as to avoid problems decreases opportunities for rehabilitation.

The program described here could not possibly have succeeded without the wholehearted and willing acceptance of the post commander, who encouraged its originators. All the levels of command and the staff sections involved were able to recognize that results could not be a great deal worse than they once were. Thus

\*From Professional Division, Office of The Surgeon General, Department of the Army, Washington, D. C. and Fort Dix, N. J.

Part I was published in November 1957 issue of this Journal.

they have been willing to assume the necessary degree of responsibility to allow their psychiatrist and their confinement officer to exercise their best judgment in the interest of improvement \* Such trust and support frequently paid off only in the long run and like the early AWOL incident, did poorly on a short time basis

Additionally the commander must be willing to listen seriously to the psychiatrist's recommendations for elimination of an individual from the service He must differentiate between the practical possibility of training an individual and his responsibility to do so He must be able to assume that the recommendations of the psychiatrist and of the confinement officer are mature and valuable recognizing that these are the only members of his command who have been able to talk to and observe this individual well enough to have a real and objective basis for arriving at any conclusion whatever

### RESPONSIBILITIES OF THE STOCKADE

The custodial personnel must exercise mature judgment and practice penology at its highest level They must attempt to suppress their tendency to become angry with the prisoners Frequently they must defend their program to others who do not recognize its value Particularly they must be mature enough to avert the reported efforts of persons who for lack of understanding wish to "put some real punishment into that place " Efforts to secure the labor of prisoners to clear the streets to rake leaves or to do more than their fair share of the post's menial tasks must be critically examined The confinement officer must be aware of and prepared to defend the bases for denying such efforts at any time the major and overriding aims of the program might thus be sacrificed Many critics will remember a day when prisoners were used in a variety of very convenient ways These memories however are also of a day when the social pressures upon the military establishment were quite different from those of the present and when the average soldier was differently motivated than is today's soldier

The confinement officer must recognize that essential to his behavior is the championing of the nondelinquent patterns of the prisoner He is not only the prisoner's custodian he is also his spokesman The prisoner must be aware of this continuously if the custodial personnel are to retain control To the degree one can the confinement officer must protect his charges from loss of dignity and individuality while demanding discipline He will get the latter if he gives the former Prisoners will tell one for

---

This program was initiated and supported when Major General John W. Harmony commanded C I I Edward P. Thomas III was Chief of Staff, Col. Richard Cameron MC was Post Psychiatrist, Lieutenant Colonel Al B. Welsh MPC was Provost Marshal, and Colonel Edward L. Ramsey III was Chief of the Confinement Office

example that they are at their most undisciplined and most defiant when waiting about the post under guard. Securing transportation for a bus to transport them may lead to a great deal of rehabilitation than hours of lecture or prison "understanding."

The stockade officer must be the kind of person in whom the prisoner can confide. He will get his best ideas from prisoners and he must give of his maturity in return. This can be demonstrated in a compassionate and understanding attitude toward the prisoner's problem or in more or less concrete ways. The prisoner is frightened when he leaves the stockade whatever the destination. A few words of advice or encouragement may be of crucial value at such a time. The confinement officer must recognize, for example, that a soldier returning to duty after months of confinement, the average soldier needs to have some free time. Arrangements to have the commander of the new unit talk to the prisoner and encouraging that officer to give the ex-prisoner an immediate pass are valuable techniques. Some ex-prisoners will not return from such a pass but a good many more will go AWOL if no pass is given. Only the confinement officer is likely to have the experience to realize this.

Finally, the stockade officer must enter into a co-operative relationship with the psychiatrist. It is most important that he recognize that he and the psychiatrist have different areas of responsibility and that the psychiatrist, too, can be wrong. When a problem that appears to have psychiatric implications arises, it is essential that the confinement officer and the psychiatrist develop a mutually agreed-to procedure and the confinement officer must carry out his portion willingly. If it is decided that a given suicidal gesture, for example, would be best handled by ignoring it, he must be willing to do so. Although the psychiatrist functions only as his advisor, the confinement officer must recognize that psychiatric findings and recommendations are technical suggestions that are perhaps best judged by a trial. Restraint in classifying a matter as a medical rather than a custodial problem is of importance. Declaring a problem to be an emergency must be done conservatively and must be on reasonable grounds. The question is not, for example, just that a given prisoner is having a temper tantrum but rather whether such a tantrum appears to be unusual. The doctor may have less skill in handling a simply angry man than does an experienced guard.

In general the confinement officer must look upon his work as that of custody, classification, rehabilitation, and disposition of prisoners. The maturity to obtain the co-operation of command and the willingness to work co-operatively with the psychiatrist are essential in the program described.

## RESPONSIBILITIES OF THE MENTAL HYGIENE SERVICE

This service must recognize that a substantial amount of its responsibility lies within the stockade. It must accept the pre-suppositions upon which stockades are operated and attempt to accomplish its end within that framework. Doing the actual work within the stockade is not only easier and more economical administratively, but it places the Mental Hygiene Consultation Service (MHCS) staff in the position of an insider in immediate and operating contact with stockade problems rather than remaining an esoteric, overcritical outside agency.

It must be kept clearly in mind that the delinquent is a special type of personality. In most of his work, the psychiatrist is able to place high reliance upon the spoken word of his patients. This is not true with the prison group, and unless he keeps this in mind he will find himself the victim of the prisoners rather than their therapist. He must guard against any tendency he has to become the champion of individuals, to expect guards to behave very differently or to look upon the behavior encountered as a legitimate response to forces within the military about which perhaps he or an individual has problems. Such reactions can only lead to his being victimized and to his opinion being rejected as unreasonable. He is dealing with psychological forces and phenomena far more fundamental than those of the middle class group with which he is accustomed to deal, and he must learn to talk the language. Prisoners are quick to recognize assumed tolerance, overinterest or fake attitudes, but they are more likely to understand if they are spoken to in their own idiom. They are not the average psychotherapy case.

The Mental Hygiene Consultation Service staff must also recognize that a prison is a place in which society imposes control upon persons who will not or cannot control themselves. Regardless of psychiatric opinions, a degree of punishment continues to be a part of the system. This leads to anxiety, depression, rebelliousness and recalcitrance among many of the prisoners and these are the natural consequences of imprisonment. The psychiatrist can rarely do much about it except to exert himself toward helping the prisoner avoid future repetition. He must also recognize that early experiences in a stockade are certain to give rise to adaptational anxiety which will, in time, be resolved. He must be aware of the normal cause of such anxiety in order to know what to expect, lest his overconcern lead him to imply that he can do more to manipulate the prisoner's situation than lies within his purview. He must differentiate between his entirely theoretical notions about delinquency and the contributions he can realistically make within the structure of the system as it exists. If he wishes to initiate changes in the system, there

may be possibilities to do so in his position as a staff officer but at any given moment he must operate within the limits of the realistically available. If he becomes too academic or unrealistically theoretical, he may be of no value to anyone.

It is necessary that he recognize that his recommendations must be based upon considerations other than his own prejudices or caprices. If he recommends separation of an individual, the commander must be provided with information upon which the action could, in each case, be justified to reviewing authorities. His unsupported opinion may be of interest, but it is not a basis for action. Although his primary duty is toward his patient, it sometimes happens that the needs of the Army and of the individual are so at odds that, if they cannot be resolved by changing the the patient, the only practicable answer is discharge. The psychiatrist must be guided by the principle that a person who can not be relied upon to do his share of the work is of no value to the Army as an employee, the social or psychiatric needs of the individual notwithstanding.

He must categorize his function carefully, remembering that certain opinions he has are based not on special skills he has as a psychiatrist but rather upon his common sense as an adult. Such items are not within the limits of his expertise. For example, he should not allow compassionate considerations to influence his psychiatric recommendations. Although he may feel that a prisoner's statement that he must be home with his ill mother is reasonable, this is not a psychiatric consideration. As a psychiatrist, he should only note the statement and attempt to show the prisoner that AWOL is a short-term and not particularly effective way of helping one's mother. The decision about what action is to be taken must be left to the commander. Although it is within his purview and perhaps responsibility to bring the matter to the attention of command, there are administrative policies and techniques for handling such matters and they do not require medical interference. To allow one's humanitarianism to contaminate one's staff relationships can only lead to casting doubt upon the more purely professional functions that do legitimately belong to a psychiatric facility.

The psychiatrist must co-operate with and respect the custodial staff. His visits to the stockade must be at frequent enough intervals so that the normal prisoner is handled in a routine manner. This policy should avert the mass of emergency referrals. On the other hand, if the stockade officer believes that a problem is an emergency, the psychiatrist must be available to see the prisoner immediately. The physician will be surprised, if he utilizes this principle, to discover that more frequently than not an experienced guard is correct if he calls a prisoner psychotic. If the psychiatrist cannot be depended upon, the custodial person

nel will have to "cover themselves" by more liberal declaration of states of emergency. He must recognize that although he gives orders in a hospital he makes suggestions under these circumstances. Sometimes because of factors beyond his knowledge and control these suggestions cannot be honored. Nevertheless, he must work co-operatively with the confinement officer and must attempt to arrive at mutually satisfactory methods of operation.

A smoothly functioning routine is an essential to this program. It may more effectively than any other influence make it evident that this anxiety, that reality need or this depression are expectable and ponderable. A variety of techniques will be used to attempt to get around the routine. If at all possible these should be discouraged. The prisoner who appears without an appointment, the prisoner referred by the dispensary physician, the prisoner who makes a request to see a particular person at MICS are all suspect. In the main such a person is seeking a special handling one cannot really give him. These individuals should be turned away and required to follow the usual procedure. This is of course possible only if they would be seen in the normal course of events.

The major area in which the routine can be defeated is sick call. Physicians will persist in wishing to treat the normal anxiety of the prison population. Consequently, the dispensary physician should be encouraged to send such patients away with instructions to await their normal and routine interview. If the liaison with the custodial staff is proper that staff should not have to send prisoners to sick call for purely psychiatric reasons. In his search for special handling, however, the prisoner will quickly sense and exploit a way to circumvent the system frequently as part of an effort to defeat the administration.

In practical fact the mass of the work done in the program is done by social workers. They interview all new prisoners after trial and make an effort to interpret the prisoner's behavior to him. Reality problems such as concern for family, allotments and other such matters are also gone into. The interview is brief, but in it the social worker attempts to get the prisoner to examine his own behavior and search for its causes. He also indicates interest and acceptance. The most important function of the interview, however, is to lay the groundwork for the remainder of the program. This interchange between prisoner and social worker provides an experience in which acceptance is offered and an opportunity for coming to terms with the administration is provided. The prisoner's conforming attitudes and behaviors are emphasized. The prisoner is shown that lack of social conformity has been of little value to him but the essence is that such antisocial attitudes are in this interview as they are in other contacts with the administration simply not the basis on which transactions are allowed.

to take place. The social worker may see a prisoner a second or third time but, in any event, he does not recommend appearance before the Classification Board until there is a marked evidence of change in attitude. A similar change must occur before clemency is recommended. If there is no change, the social worker may make no recommendation whatever.

When and if a person has had three courts martial or if he is a psychotic, a homosexual, an alcoholic, or a drug addict, he is referred on to a psychiatrist. The psychiatrist hospitalizes the psychotic, who then becomes a medical disposition problem. The psychiatrist recommends all others for appearance before a board of officers convened under the provisions of appropriate regulations,<sup>11,12</sup> and makes findings and recommendations for use by that board. In custodial problem cases, he recommends that early action be taken, but allows all others to complete their sentence without interference.

The social worker also sits as a member of both the Classification Board and the Clemency Board. Beyond this, the MHCS staff performs only those services at the stockade that are requested, attempting not to interfere with its routine. Although the stark and unhappy stories told to the social worker are frequently fabrications, great care is taken to assure that the individuals doing this work do not become cynical. Any reasonably believable story is checked by requesting a home conditions report from the American Red Cross. Such information is not only of value to the psychiatric staff, but also may be helpful to the commander in arriving at administrative decisions.

Finally, the MHCS must recognize that although much that goes on pertains to psychiatric considerations, it by no means follows that the MHCS always has a contribution to make, to say nothing of a solution to offer. When this becomes evident, such contributions as may be appropriate are made, and the staff carefully withdraws from the situation. While no one proposes that modern systems of justice are perfect, psychiatry has not yet reached the point of having a really better answer to some problems.

### TECHNIC OF OPERATION

Twice weekly, the confinement officer prepares a list of the newly sentenced prisoners in the stockade. This is forwarded to the MHCS through the appropriate personnel section which adds essential data such as the number of courts martial, the commander's opinion, or cetera. A social work officer has two periods of consultation a week at the stockade during which he sees every person so listed. He investigates the background of the case, discusses it with the commanding officers where indicated, and makes a report to the stockade commander. Individuals referred on to the psychiatrist are seen routinely the following week during

one of two regularly scheduled periods for psychiatric consultation, also held at the stockade. There is liberal, informal consultation with the confinement officer and the decisions arrived at, although a part of the psychiatrist's report, are usually the concurring opinion of the psychiatrist and the confinement officer. During these periods, the psychiatrist also examines any person or group referred by custodial personnel, does pretrial sanity determinations on the request of The Judge Advocate General (the number of persons being tried is such that routine pretrial evaluation is impossible) and sees persons referred by the dispensary, The Inspector General or the Special Inquiries Section of The Adjutant General.

In situations in which the recommendation is for clemency, transfer to the rehabilitation company, or special work assignments and limitations, or when it is upon other matters that constitute recommendations to the confinement officer the final report is provided to the confinement officer and is used by the various boards. The confinement officer and the psychiatrist work together particularly closely in arriving at techniques for handling persons given to hysterical fainting, paralysis, vomiting and other evidence of individual rejection of or failure to adapt to the confinement situation. Similarly they work out procedural techniques for dealing with cliques, "kangaroo courts" and tantrums of various types.

In cases where elimination from the service is recommended, the report is provided to Post Investigations where it is heard immediately if such is the recommendation, or it is placed in a suspense file to be heard at such a time as to assure that the individual will not return to an active duty status. All reviewing agencies expedite their handling in order not to impede the orderly flow of the process. Table 1 provides data concerning the characteristics of a sample of 500 cases seen by the MUCS at Fort Dix. N J.

### EFFECT OF THE PROGRAM

*Criteria of efficacy in any rehabilitative procedure are difficult to establish.* In the case of the rehabilitation of delinquents, the problem is made to appear even more bleak by the modesty of results under the best of circumstances. There are, however, indexes available for the evaluation of an over all stockade operation and such data are presented here. It is impossible to establish which of these effects can be ascribed to the psychiatric program *per se*. A tendency exists to overevaluate the psychiatric contributions and to underrate the value of custodial staff attitudes, the availability of work programs and staff and command co-operation. There is probably an even more significant tendency to fail to recognize the importance of co operation and mutual respect among these agencies. Although the custodial personnel

the relationship between the custodial personnel and the prisoners is such that work programs will be participated in by the prisoners with sufficient willingness so as to be efficacious.

Figure 1 indicates the proportionate distribution of classes of custody. It is to be noted that before the program was inaugurated nearly 20 per cent of the prisoners were in maximum custody and fewer than 10 per cent were on parolee status. About 70 per cent were in medium or maximum custody, seemingly indicating marked dependence upon area restraint. After the program was put into

AVERAGE QUARTERLY DISTRIBUTION OF CUSTODY GRADES  
(PERCENT OF TOTAL STOCKADE POPULATION)  
1 JULY 1954 31 DECEMBER 1955

operation maximum custody fell as low as 5 per cent and never rose above about 10 per cent. Maximum plus medium custody accounted for 50 per cent or less of the population during most of the reported period. Parolee status was awarded to from 20 to 25 per cent of the population while during most of the period minimum custody plus parolee accounted for about one half of the population. In general the data seem to indicate a substantial diminution in the use of area restraint.

The question arises as to whether this easing of restraint led to an increase in restiveness. Sick call represents one traditional way of expressing dissatisfaction. The sick call rate at a post stockade is usually considerably greater than in the post at large. Figure 2 indicates that starting with a rate more than seven times

that of the post, there has been a general diminution to less than five times the general rate.

COMPARATIVE SICK CALL RATES EXPRESSED AS INCIDENCE PER 1 000 PER ANNUM  
1 OCTOBER 1955-31 DECEMBER 1956

Fig. 1

Such restiveness and resistance to the general discipline of the stockade might be expected to manifest itself in an increased number of disciplinary actions within the stockade itself. Figure 3 indicates the marked diminution in the use of both disciplinary segregation and court martial. These measures have been regarded by the custodial personnel as much less necessary.

The incidence of escape from either the stockade proper or the rehabilitation company does not lend itself to graphic representation. In general, however, escape from the post stockade has remained relatively constant in spite of the diminution of "custody grade consciousness." The rate approximates or is lower than the post AWOL rate. The small size of the rehabilitation company is such that one elopement produces a significant value when expressed as a rate per thousand per annum. Since the early incident of almost total elopement, as long as 8 months has elapsed without an escape, and during the remaining period one or two prisoners are the maximum to escape during any quarter. This is in spite of the Christmas home parole policy described.

#### Criteria of Psychiatric Results

Psychiatric results have been even more difficult to evaluate. Obviously, with a program of this sort, the nonpsychiatric incidence rate, if measured by the number of cases reported, approach

es 100 per cent. The referral rate has never actually reached 100 per cent, however. This is because individuals awaiting appearance before a general court martial are seen only on the request of the Office of the Judge Advocate General. Also during this period personnel of the overseas replacement pipeline were seen only on specific Command referral. The incidence of referrals to MHCS from the stockade expressed as the rate per 1 000 per annum before and after initiation of this co-ordinated program, is compared in figure 4. The percentage of total MHCS cases opened that were generated in the stockade is also indicated. It can be seen that the number of cases opened has about doubled. It is believed, however, that the amount of time and effort expended on referrals from the stockade has remained about the same. Such a co-ordinated program makes it so much easier to achieve results that more can be done for more people at less expense in time and effort. The types of cases encountered show only the expectable preponderance of antisocial types of character disorder. The incidence of psychosis and of other psychologically determined symptoms is not significantly different than the incidence elsewhere on the post. Transfers to the rehabilitation company have never been made in large numbers. The census of that operation has remained more or less constant at about one tenth of the total population. This is reflected in figure 5. The percentage of these known to be nonrecidivists on a 90 day follow up is reflected in the broken line.

Data obtained from Post records. Post No. 100, 1000

Individuals admitted to stockades invariably have a high administrative discharge rate. The occurrence per quarter expressed as an incidence per 1 000 per annum of this disposition in this group is reflected in figure 6 and compared with the over all post rate. It is to be noted that a sharp early rise tended to level off toward the level which existed prior to the onset of the program.

The recidivism rates are reflected in figure 7. Of significance is the disappearance of recidivism beyond 5 times and the near disappearance of recidivism beyond 4 times. Approximately 18 per cent of the population had had 3 or more previous courts martial prior to the onset of the program which figure has dropped to approximately 5 per cent. The incidence of first offenders has not changed significantly.

The number of confined individuals per 1 000 mean post population was greater in this stockade than is typical of posts army wide. To some degree at least this reflects the presence of a substantial number of individuals from other posts apprehended in local areas and confined at Ft. Dix for disposition (table 1). The program described has however been accompanied by a

QUARTERLY RATE OF ADMINISTRATIVE DISBURGES (AREL) BY AR 635 200

gradual diminution in the number of prisoners per 1,000 mean post population which now approaches more nearly the average post's experience. This is reflected in figure 8. This incidence has dropped from a high of 18 prisoners per 1,000 troops to about 10 prisoners per 1,000 troops. The establishment of an overseas replacement station in the middle of this period produced no appreciable change in the data.

NUMBER OF PRISONERS PER 1 000 POST POPULATION

### SUMMARY

The social atmosphere of modern America and the pressures presently impinging upon the commander of a post in the U S Army are such that a stockade must be operated in a fashion that will avoid incidents leading to danger to life or limb. In addition, this group contains a high percentage of persons of low military potential whose disposition is economically advantageous once this has been clearly established. A program of mutual co-operation between stockade and psychiatric personnel appears to be an effective device to attain this end. A constructive program for the rehabilitation of those who can be reclaimed is described. This latter appears to avert the confirmation of delinquent behavior as a persistent behavior pattern which leads to an unnecessarily high loss of personnel. The results of this sample program are presented.

# EVALUATION OF A PACKAGED RETENTION ENEMA IN PREPARATION FOR PROCTOSIGMOIDOSCOPY

FRANK E. ABOT Captain USAF (MC)  
LIEUTENANT COLONEL USAF (MC)  
FRANCIS W. SUTHERLAND Captain USAF (MC)

**P**ROCTOSIGMOIDOSCOPY is an essential diagnostic examination for patients with colonic and anorectal disease. More recently it has been used as an integral part of the routine physical examination on all patients over 35 to 40 years of age. In spite of its importance, it has been looked upon by patients, ward personnel, and many physicians with disfavor. This has primarily been due to the problem of obtaining an adequate preparation. Traditionally, patients are prepared with enemas or laxatives, both of which are uncomfortable, aesthetically repellant, and involve the expenditure of considerable time. It is not unusual for the patient to spend at least 10 minutes in an uncomfortable position, most of which time is taken up by the unhappy physician laboriously scrubbing or aspirating feces, in order to obtain a clear view. In many instances the self-prepared patient, having spent many uncomfortable hours, comes for the examination so poorly prepared that he must be rescheduled and attempt the onerous chore all over again. This often has resulted in his deferring the examination, such delay may at times prove to be tragic.

In the course of investigating the incidence of rectal or recto sigmoid polyps in a large group of asymptomatic young airman, we encountered considerable difficulty in obtaining adequate preparations and, frequently, reluctance on the part of the subjects for re-examinations. We therefore decided to investigate the effectiveness of a recently introduced packaged retention enema preparation of sodium biphosphate and sodium phosphate. Our results were so satisfactory that we have adopted it as the routine preparation for proctosigmoidoscopy in our active proctoscopy clinic. This communication is a report of the results of our study.

From U. S. Air Force Hospital, Lackland Air Force Base, Tex. Dr. Abbot is now at 163 Grove St., Waterbury, Conn.

Retention enema containing 16 grams sodium biphosphate and 6 grams sodium phosphate in each 100 ml. supplied by the C. B. Fleet Co., Inc., Lynchburg, Va.

## MATERIAL AND METHODS

Subjects for this study were 333 asymptomatic young nirmen being investigated for incidence of polyps, 50 foreign language students examined for enteric parasites, and 283 patients referred for a proctosigmoidoscopic examination with gastrointestinal symptoms. No preliminary preparation was made. The majority of the subjects were examined in the first part of the morning for the sake of convenience, but many were examined in the late afternoon on the day of their first visit to the referring clinic or hospital ward.

With the subject in the knee chest or left lateral position, the entire contents (133 ml) of the plastic "squeeze bottle" was introduced into the rectum. The subject was instructed to retain the enema as long as he was able and then to remain on the commode until he felt his bowel had moved completely. Proctosigmoidoscopy was done at varying time intervals following the enema. The following data was recorded: (1) Time enema was retained; (2) time between enema and examination; and (3) the presence and type of symptoms produced by the enema.

At examination the adequacy of the preparation was graded as excellent if the rectum and rectosigmoid were completely clear of feces; good if the small amount of liquid or solid feces present was easily removed; poor if a large amount of feces necessitating much swabbing or suction was encountered. When preparation was so poor as to prevent or limit the examination, a second enema was given. The degree of hyperemia, spasm, and mucus present was graded by the method of Almy and Tulin.<sup>4</sup> In a certain number of patients, swab specimens of rectal contents were examined microscopically for ova and parasites. In another group stool specimens obtained both spontaneously and from enema results in addition to rectal swabs were examined.

## DISCUSSION

Preparations were excellent in 526 subjects (78.5 per cent), good in 120 (18.5 per cent), poor in 20 (3 per cent). Of the latter 7 (1 per cent) had to have repeat enemas, all of which resulted in excellent preparations. The average time the enemas were retained was 5 minutes, ranging from 1 to 12 minutes. The average interval from enema to examination was 28 minutes, with extremes of 4 and 90 minutes. There was no correlation between either the retention time or the interval until examination and the quality of the preparation. Thirty-seven subjects (5.5 per cent) complained of mild cramps resulting from the enema. The majority simply experienced a compelling urge to defecate. Two hundred and five subjects (31 per cent) were found to have increased amounts of mucus (the great majority 2 plus), 175 (27 per cent)

had hyperemia of the colonic mucosa (mostly 2 plus), and 65 (12 per cent) were found to have spasm 2 plus being the majority degree. There was no correlation between the time of retention or interval of examination, and the presence or degree of these findings. They were usually found alone, and only very seldom were associated with others. Spasm and hyperemia were associated more often than the other changes. The more than two thirds with no change showed a widely patent rectum and rectosigmoid of healthy appearance into which the proctosigmoidoscope was introduced with ease and a minimum of discomfort. The average distance examined in all subjects was 5.7 inches. There was no correlation between this and the quality of preparation.

Two hundred and twenty of these subjects had rectal smears smeared examined for ova and parasites. Twelve of these were positive for parasitic ova and cysts. Five were characterized as having excellent preparation, seven were good. Fifty language students, mainly Asiatics, had rectal smears examined microscopically following the enema, and also spontaneously passed stool specimens examined by concentration technic. Three of the smears were positive, 29 of the stool specimens were positive for parasites. All of the preparations were characterized as excellent. In addition, the stools of 70 subjects obtained as returns from the enema were subjected to examination by concentration technic, 16 of which were positive for parasites. Also, 3 Puerto Rican patients had mucosal biopsies, positive for viable *Schistosoma* ova.

### CONCLUSIONS

No comparative figures on the quality of preparation in patients prepared traditionally for a proctosigmoidoscopy are available. Three hundred consecutive records of our routine proctosigmoidoscopies were studied with this in mind, but insufficient characterization of preparation was noted. There is no doubt in the minds of those of us who have experienced both methods, however, that the majority of preparations by the enema described are infinitely superior to those by traditional methods. The field is completely clear almost 80 per cent of the time, and with the lack of spasm reported here in 88 per cent, the instrument may be introduced rapidly and relatively comfortably. The lack of prior preparation and the consequent availability of the examination at any time of the day encourages the use of this procedure and speeds diagnosis of anorectal conditions. Ease and lack of

Positive smears showed *Entamoeba coli* cysts, ascaris ova, *Trichomonas hominis* protozoa, and *Iodamoeba* cysts. Stool examinations by concentration technic showed ascaris ova, hookworm ova, *Strongyloides* larvae, *Trichostrongylus orientalis*, *Clonorchis sinensis*, *T. hominis*, *Giardia lamblia*, chilomastix, *Entamoeba histolytica*, *Iodamoeba bütschlii*, *Endolimax nana*, and pinworm ova.

discomfort during preparation encourages patient co-operation. This preparation also provides for better detection of small lesions and biopsy may be accomplished readily. The average distance examined in 300 patients prepared traditionally was 8.6 inches compared with 8.7 inches in our subjects.

Our results show that adequate rectal smears for parasitic trophozoites, ova, and cysts should not be expected from this preparation. The majority of our positive smears were from inadequate preparations. It may be inferred from the large number of positive stool examinations with negative rectal smears in preparations found to be excellent, that this method of preparation is too thorough. On the other hand reliable fresh stool specimens may be obtained by the retention enema. It is an excellent preparation for mucosal biopsies for *Schistosoma ova*.

The mechanism of action of the Fleet enema is not known. Of interest in this regard are two patients not included in this series. Both had saddle anesthesia with cord bladder—one from metastatic carcinoma of the breast to the sacrum, the other from trauma to the cord. Both were given the packaged enema for fecal impactions. Neither had an urge to defecate, nor did fecal returns result. It may be inferred that the enema initiates a local rectal reflex for defecation.

### SUMMARY

Of 666 patients given Fleet enemas as preparation for a proctosigmoidoscopy 78.5 per cent had excellent preparations, 18.5 per cent, good, and 3 per cent poor. This preparation may be given quickly, without prior preparation anytime of the day. It causes little discomfort. This method is recommended to replace other traditional preparations for proctosigmoidoscopy.

# CONGENITAL DERMAL SINUS AND CYST

RECEIVED 1 OCT 1941  
HUGHES 1 - 113  
LATERAL 1 1113 11 1113

**N**O SUBJECT in the field of congenital pathology is more confusing than the nomenclature and classification of the "congenital tumors". The clinical life span of intracranial and spinal "dermoids" is especially ambiguous from the viewpoint of pathology.

The relative infrequency of congenital tumors has led in many instances to the presentation of lesions of widely varying microscopic appearance as a single group. Thus, from the anatomical standpoint, intracranial "dermoids" often have been grouped with the teratomas, and by inference have been classified as true neoplasms. This grouping would appear to be incorrect pathologically and might lead to errors in clinical management. Illustrative cases will be presented.

## PATHOGENESIS OF TERATOMAS

Sweet<sup>1</sup> collected 156 cases in 1940 and classified them as dermoid, teratoid, and teratomatous intracranial tumors in 12 different groups according to location. He pointed out the great difficulty in classification stating that these tumors consisted "pathologically of a series of gradually increasing complexity, and that any separation of them into subgroups must be at arbitrary points". Sweet further called attention to the fact that Ewing<sup>2</sup> had discarded the idea of metaplasia of nonectodermal structures from the connective tissue elements of the skin (the so called "mixed tumors") in favor of the concept of a natural unfolding of embryonal cell potencies, and that these tumors were now known as teratomas.<sup>3</sup>

Willis<sup>4</sup> gave the literal meaning of teratoma as "a malformation which is also a true tumor" and defined teratoma as a "true neoplasm composed of multiple tissues foreign to the part in which it arises". In discussing the hypotheses of origin of teratomas, he stated that the most popular view is that these growths represent distorted fetuses, derived either from included twins of the

From U. S. Naval Hospital, Chelsea, Mass. Comdr. Crue is now assigned to U. S. Naval Hospital, San Diego, Calif.

bearers or from parthenogenic proliferation of the bearers' own germ cells. Willis thought this was incorrect, however, because the common sites of teratomas are not the sites of parasitic twins. Most teratomas arise during early stages of development when their bearers have no mature germ cells capable of parthenogenesis. Topographic study of teratomas shows that while some times highly organized they are not fetal in form, and the view that they represent embryos ignores the fact that they are true neoplasms with powers of independent growth not seen in "amorphi" or parasitic twins. Instead, teratomas may represent neoplasms in areas of tissue which escaped from the action of the primary organizer during early embryonic development. The site of distribution of teratomas points to the operation of growth disturbances emanating along the primary axis.

### SYNONYMS

Distinct clinical and histologic entities have come to be recognized among the congenital tumors. This has led to different terms such as chordoma of the clivus of the base of the sphenoid, craniopharyngioma or cyst of Rathke's pouch, and teratomas of the pineal region. Confusion has been compounded by the various synonyms used by different authors. Classification according to microscopic determination of the number of germ layers has led to terms such as monodermoma, bidermoma and tridermoma. Classifications according to predominant tissues (ovarian goiter) and the organ where the tumor arose (cholesteatoma of the ovary) have been used. The term "cholesteatoma" may be used to describe the gross appearance of several different entities within the cranial cavity. Degrees of malignancy, on both a clinical and a histologic basis, led to terms such as teratoblastoma, embryoma, teratocarcinoma, and embryonic carcinoma. Even common terms often are misused clinically. For example, the superficial epidermoid is often called a "cyst" or "sebaceous cyst," when in reality it contains only desquamated squamous cells.

If no exact classification could be made the ending "oma" often became changed to "omatous." The suffix "oid" originally meaning "form" from the Greek has come to mean "not quite like, but almost."

Various other terms were described in an article by Black and German<sup>9</sup> and in a review by Sachs and Horrax.<sup>10</sup>

### TRUE NEOPLASMS NOT SEPARATED

In 1946 in an article on cystic teratomas and teratoid tumors of the central nervous system in infancy and childhood, Ingraham and Bailey<sup>11</sup> listed 15 cases: 8 intracranial and 7 intraspinal. This series apparently included 3 "dermoids" of the posterior fossa. These authors stated "Since certain tumors of the central

under discussion but for not a truly different general principle. It has been recognized that certain types of teratoma have been excluded as being ectodermal. We have included the dermoid cysts because they present many general features similar to those of the cystic teratomas and because it is a belief that they are histologically a developmental stage in the formation of the teratoma.

In 1930 Black and Coombs<sup>11</sup> related as a title to congenital tumors with the statement "The epidermoid dermoid teratoma and its anatomical tumors of the central nervous system: a congenital neoplasm" that one of particular original pathological and embryological interest.

Others do not agree that the "dermoid" of the present formula is a neoplasm.

Willis<sup>12</sup> stated in 1951 that a teratoma is a true tumor and, unlike a simple malformation, has powers of progressive growth either in benign or malignant form. Teratomas should be distinguished from non-neoplastic malformations of all kinds, whether relatively simple heterotopias of particular tissues or complex malformations such as double monsters or imperfect twins. Sequestration dermoid cysts of the skin or cranial cavity, branchial cysts, and many other developmentally misplaced and supernumerary parts and tissues (Albrecht's "hamartomas") all constitute masses of multiple kinds of tissue in the wrong places but are not neoplastic and quite unrelated to teratomas.

Dermoid cyst is a frequently used synonym for benign cystic teratoma of the ovary when the dermal elements predominate. If a thorough search is made, tissues other than skin can usually be found. The same name is also applied to intracranial skin-lined cysts. It appears, however, that most intracranial "dermoids" probably are not true neoplasms. To prevent any unwarranted connotation, the term "congenital dermal sinus" or "congenital dermal cyst" would seem preferable.

#### PATHOGENESIS OF CONGENITAL DERMAL SINUSES AND CYSTS

Ingraham and Matson<sup>13</sup> pointed out that since the neuroectoderm separates from the epithelial ectoderm along the dorsum of the embryo, it is natural to expect that persistent epithelial defects may extend to any depth from the deeper layers of the skin to the substance of the central nervous system, and, because this midline fusion begins in the middle of the embryo and proceeds both cranially and caudally, there is chronologically more opportunity

for cutaneous defects to occur in the lumbosacral and suboccipital regions. This correlates clinically with the frequency of occurrence of congenital defects along the midline at these two locations.

This pathogenic mechanism would seem to apply whether the sinus or stalk connection to the surface remains or disappears. If the defect occurs early in embryonic development, with "pinching off" at about the third or fourth week of fetal life, then a simple "epidermoid" might be expected to result. Just when the accident occurs that includes other elements and gives rise to a "dermoid" is not definitely known nor is it known at just what stage "cell rests" occur that later give rise to true neoplasms, the teratomas. Because of their autonomous growth they are usually thought of as embryonic. Also unknown is the mechanism whereby they can remain in situ for years and then in some cases give rise to rapidly growing malignancies. Just where a similar mechanism fits in for the production of meningoceles or aplasias and what brings them about is also still largely a matter of conjecture.

In the sacral area the commonest defect is the dermal sinus. This is not an infrequent finding, even on routine examination, and it is now generally recognized as a congenital defect.<sup>13</sup> It is usually entirely dermal so that the term "pilonidal sinus"<sup>14</sup> is superior to "benign sacral cyst teratoma." Only a small percentage have a residual connection with the spinal canal, and surgical removal of the pilonidal sinus generally is performed only after the lesion causes symptoms, usually from local infection.

There also may be true neoplasms in the sacral area. These congenital tumors may be either benign or malignant, and may be found in infancy or in the adult. Thus congenital defects as well as congenital neoplasms (the true teratomas) may affect the spinal canal at any position along the spinal axis.<sup>15</sup>

If these congenital dermal sinuses of either the anterior or posterior neuropore are not classified with the teratomas but are considered developmental defects they might be expected to occur in relation to other types of developmental anomalies. Even teratomas and lipomas are found not infrequently in association with other central nervous system anomalies.

In the past two years five patients with intracranial dermal cysts have undergone craniotomy at this hospital. In one additional patient this clinical diagnosis was made but operation was not advised. Four of these cases were somewhat unusual and seemed of interest in view of the above discussion of pathogenesis.

### CASE REPORTS

**Case 1** A 4½-month old white boy was admitted to the hospital for elective neurosurgical excision of two occipital masses both present

since birth. The child was a product of normal pregnancy, labor, and delivery. He had been in excellent health except for two episodes of mild otitis media. The head of the infant developed normally and he exhibited no other symptoms of increased intracranial pressure had occurred.

Physical examination was normal except for the occipital lesions (fig 1). The upper mass was 2.5 cm in diameter, smooth, and translucent well. It had a thin wall and was cystic. The fluid contents could be compressed into the cranial cavity easily and a bony defect could be palpated. The lower mass was 3 cm in diameter, did not transilluminate, and was covered with thickened skin and hair. The contents were firmer and could not be displaced.

Figure 1 (case 1) Encephalocele above dermal cyst below Sinus tract is lateral to lower mass.

At operation a previously undetected sinus tract was found after shaving at the lateral edge of the lower mass. A probe could easily be passed through the sinus to the bone but not beyond the skull.

The upper mass was removed first and proved to be a meningocele containing no nervous tissue grossly. The wound was completely sutured then the lower lesion was excised. It proved to be much thicker walled and was filled with sebaceous material and hair. The accompanying sinus tract ended blindly in a stalk that appeared to go through a very small opening in the occipital bone. In view of the lack of neurologic symptoms and the contaminated nature of the external wound the stalk was transected at the level of the outer table and intracranial exploration of the posterior fossa was not carried out.

Postoperatively the patient recovered promptly. He was discharged on the eighth postoperative day.

Pathologic examination verified the operative finding that the upper lesion had a dural lining while the lower one was a typical dermal cyst.

*Comment.* It is believed that this case represents two associated congenital anomalies and that this type of dermal cyst can in no way be considered a neoplasm. As Logue and Tilt<sup>11</sup> have stated, these lesions enlarge only "as a result of the secretion of sebaceous material and the desquamation of epithelium within." That symptoms from an intracranial portion of the dermal abnormality may develop in the future is admittedly a calculated risk.

**Case 2.** A 13 month-old white girl was admitted to the U S Naval Hospital Chelsea Mass because of a lesion of the scalp present since birth. Pregnancy, delivery and postnatal development had been normal. The only physical abnormality consisted of a mass in the midline in the midparietal area. The mass was approximately 3 cm in diameter and was raised about 2 cm with a definite large central dimple. There was a pronounced port wine discoloration of the surrounding skin.

Roentgenograms revealed a small bony defect in the midline slightly anterior to the soft tissue mass and also anterior not only to the lambdoid suture but also to a second suture line formed by a wormian bone (the so-called incaral bone).

It was thought clinically that this was a typical congenital dermal sinus but more anterior than usual. It was not known whether a sinus tract from this midparietal area led to the posterior fossa or ended above the tentorium.

At operation the skin lesion was excised and bone was removed so that the underlying stalk could be followed intracranially. The sinus was found to go through the dura tightly adherent to the left side of the longitudinal sagittal sinus. A dural flap was elevated over the left parietal cortex. A probe was inserted in the sinus and surprisingly a sharp posterior angulation was found. The probe was inserted with ease

to a depth of 4 cm. The air appeared to be between the lateral lesser part of the falx and was visualized downward between the tentorium for a depth of almost 1 cm. when the left parietal cortex was torn at a lateral level. No more was seen. Further exploration along this plane was not considered to be warranted. 1 cc of oil (Lipiodol) and 1 cc of air was injected into the sinus tract, the sinus filled with air and the operation terminated.

Postoperative roentgenogram (fig 2) denotes such an accumulation of dye within the posterior fossa. This was believed to be within a "dermal cyst."

Figure 2 (case 2). Posteroanterior and lateral roentgenograms after injection of Lipiodol into sinus tract.

The patient did well postoperatively. Forty eight hours later roentgenography was repeated and revealed that the Lipiodol was scattered throughout the posterior fossa with an accumulation pooled inferiorly apparently in contact with the occipital bone. A roentgenogram of the lumbar spine showed dye in the lumbar spinal canal. A pneumoencephalogram was carried out under general anesthesia and air was found to enter the area in the posterior fossa previously believed to be a "dermal cyst" (fig 3). The patient was taken to the operating room for exploration of the posterior fossa.

At operation the dura over the cerebellar hemispheres appeared normal. Upon turning a dural flap the arachnoid membrane was kept appeared normal and beneath this thin covering spinal fluid

*Figure 3 (case 2). Posteroanterior and lateral pneumoencephalograms, showing air in area of "cyst."*

of air and droplets of Lipiodol could be seen. The arachnoid was opened widely. It was then apparent that the cerebellum was abnormal. The two normal appearing hemispheres could be retracted apart and were separate except at the uppermost ventral part where they were connected across the midline by several large veins. In view of the patient's lack of symptoms it did not seem justified to explore this area further although the aplasia of the vermis and midline structures seemed almost complete. The under surface of the posterior part of the tentorium was easily visualized. No dermoid cyst was found. Instead an inverted funnel was seen in the midline where apparently the "dermal sinus" widened out and emptied directly into the subarachnoid space (fig 4). One large vein traversed the opening in the midline and several small bridging veins descended to the veins previously seen in the midline in the superior aspect of the cerebellum. The operation was terminated.

Postoperatively the child did well and was discharged on the thirteenth day.

The pathologist's report on the specimen of skin and upper sinus tract removed at the first operation was "consistent with cicatrization wall of dermoid cyst."

Review of the slides (fig 5) revealed that normal skin of the scalp surrounded a central depressed area. There was loss of almost all the hair follicles, sweat glands, and sebaceous glands in the depressed area.

*Figure 4 (case 2) Drawing of sinus tract reconstructed from roentgenograms and surgical findings. (Mid sagittal view)*

and the normal collagen of the dermis was disorganized. A striking feature was the great number of dilated tortuous thin-walled blood vessels although these did not appear to represent a true hemangioma. The epidermis was continuous on the surface and did not extend into a sinus. The dermis was scarred and was continuous with an underlying cicatricial stalk containing no skin elements. There was a cellular layer, resembling dura, around the stalk. The findings were consistent with those of a meningocele although it might represent in part, an abortive congenital dermal sinus.

*Comment.* It is thought that this was an unusual case from the standpoint of pathogenesis. Clinically the external lesion and sinus tract appeared to be typical of a congenital dermal sinus.

*Figure 5 (case 2) Photomicrograph of section through externally presenting lesion (Hematoxylin and eosin stain  $\times 100$ )*

By emptying into the subarachnoid space it had aspects of a meningocele. The congenital nature of the defect was further shown by the associated aplasia of the midline structures of the cerebellum.

**Case 3** A 7 week old white girl was admitted to this hospital because of an occipital mass present since birth (fig 6). Pregnancy delivery and postnatal development had been normal. Physical and neurologic

*Figure 6 (case 3) Occipital mass with "port wine" discolored area on superior surface*

examinations revealed a firm rounded mass  $\frac{3}{4}$  inch in diameter in the midline of the occiput. It did not transilluminate and did not pulsate with heart beat, respiration or crying. An associated "port wine hemangioma" was present at the base of the mass.

Röntgenograms of the skull revealed a small radiolucent defect 5 mm in diameter, in the occipital bone under the center of the overlying mass. Ventriculograms failed to show any abnormality except small occipital ventricular horns bilaterally symmetrical which were considered within the limits of normal variation. The diagnosis of encephalocele was concurred in by all observers and the patient scheduled for craniotomy.

At operation the mass was discovered to be a "dermoid cyst" when the tumor burst and sebaceous material escaped. The stalk through the bone went through the meninges also and ended blindly in the tissue of the cerebellum.

Following operation the child did well and was discharged on the twelfth postoperative day.

The pathology report described the gross specimen as a cylinder of skin with an attached underlying cyst filled with hair and sebaceous material measuring 2.5 cm in diameter. The diagnosis was "dermoid cyst occiput."

Review of the slides (fig. 7) revealed that the cyst was lined by skin showing gentle papillation of the epidermis with an abundant stratum corneum. The numerous hair follicles, sebaceous glands, and sweat

Figure 7 (case 3) Photomicrograph of section through cyst. (Hematoxylin and eosin stain,  $\times 100$ )

December 1957

## CONGENITAL DERMAL SINUS AND CYST

1777

glands were mature although the intervening connective tissue was looser than normal and contained many large capillary channels. Vascular scar tissue is noted in the deep dermis at one point. The diagnosis is congenital dermal cyst.

*Comment* In retrospect the port wine hemangioma and the firmness of the occipital mass should have led to at least the suspicion of a congenital dermal cyst preoperatively. The pathologic picture was typical of a dermal cyst. The case is presented to illustrate that clinically the differential diagnosis of this condition and encephalocele is not always clear cut.

*Case 4* Recently a 13 year-old girl was referred to one of us. On routine physical examination before going overseas she had mentioned a small occipital midline skin lesion. The patient was asymptomatic and had never had any signs or symptoms of meningitis.

Examination of the scalp revealed a flat reddish lesion 4 mm in diameter and raised 1 mm. It had never bled been tender or had any known discharge. The alert pediatrician had requested roentgenograms of the skull however and on close examination there appeared to be a small bony defect 2 mm in diameter in the occipital area compatible with a sinus tract. Neurologic examination was completely negative and surgical exploration was not recommended.

*Comment* The decision not to operate was received with much discussion. The literature was reviewed and many cases were reported which pointed out the danger of this portal of entry for infection of the nervous system.<sup>11, 12</sup> A suggestion has been made that the discovery of a congenital dermal sinus might be justification for excision before any signs of infection or obstruction from an enlarging cyst occurs.<sup>13</sup> Most of the clinical literature, however, is not statistically of value inasmuch as these congenital dermal sinuses and cysts have been included with the true neoplastic teratomas. Most conclusions reached have been on the basis of very few cases or on theoretical grounds. We are not familiar with any series of occipital dermal sinuses that have been followed without resorting to surgical intervention. In this case it was believed that even the small risk of signs of infection or of obstruction from an enlarging cyst in a non neoplastic congenital defect that presumably had been present for 13 years. This viewpoint admittedly is not presented with any conviction.

That the morbidity and mortality associated with these congenital dermal sinuses, treated or untreated, are important cannot be denied, even though they are relatively rare lesions. Although this may be a matter of some practical clinical importance, a recent text on neuropathology still lists these "dermoid cysts" under the chapter on neoplasms and not as congenital malformations.<sup>14</sup>

## SUMMARY AND CONCLUSIONS

The intracranial "dermoid" of the posterior fossa whether largely intracranial or external often is associated clinically with the teratoma group of neoplasms. It is believed that these lesions should be considered congenital defects and that they are not neoplasms. It is suggested that the term "dermoid" be discarded in favor of "congenital dermal" sinus or cyst. These lesions should be considered as a separate entity so that statistically reliable conclusions regarding their natural history may be reached.

Four cases of congenital dermal sinus or cyst of the posterior fossa are presented. The first case illustrates that the dermal cyst may occur in association with another type of congenital anomaly. The second case indicates that these lesions cannot always be distinguished clinically from other congenital anomalies. The third case demonstrates that the external dermal cyst may be mistaken clinically for an encephalocele. The fourth case in which only a presumptive diagnosis could be made, was presented to illustrate how little is actually known about the expected course of events in some instances of dermal sinus.

## EFFECTIVENESS OF NEW ORAL DIABETES TABLETS

"The effectiveness of these is greatest in older and milder diabetes. It should be stressed that it has been found almost totally ineffective in patients whose diabetes began in childhood or adolescence and in adult patients with severe diabetes. In such cases attempts to substitute oral treatment for insulin may lead to serious consequences. While extensive trials in several thousand cases have thus far not been found to show any serious toxicity the investigators and clinicians who have worked with the drug cannot say at the present that more widespread use over periods of several years may not be somewhat hazardous. Fortunately the manufacturer and all physicians are alerted to these possibilities and we may be sure that results of treatment will be closely scrutinized for some years to come so that any possible untoward effects may be prevented or stopped in good time. It is important to emphasize that rigid dietary management of diabetes remains the keystone of the arch of treatment. It is generally agreed that substitution of the new drug for insulin in patients who have received the latter should be very closely supervised and may necessitate hospitalization for the initial period. It will take many years to judge the effect of any such drug on life expectancy and occurrence of complications in diabetes. During the past few months a still newer drug N<sup>1</sup> beta phenethylformamide in diabetes. This substance does not belong to the tolbutamide chemical family. The available information on DBI is too scant as yet to allow any preliminary conclusions."

# FIRST AID MEASURES IN POISONING

The aim of first aid measures is to help prevent absorption of the poison. SPEED is essential. First aid measures must be started at once. If possible, one person should begin treatment while another calls a physician. When this is not possible, the nature of the poison will determine whether to call a physician first or begin first aid measures and then notify a physician. Save the poison container and material itself if any remains. If the poison is not known, save a sample of the vomitus.

## MEASURES TO BE TAKEN BEFORE ARRIVAL OF PHYSICIAN

### I. Swallowed Poisons

Many products used in and around the home, although not labeled "Poison," may be dangerous if taken internally. For example, some medications which are beneficial when used correctly may endanger life if used improperly or in excessive amounts.

In all cases, except those indicated below, REMOVE POISON FROM PATIENT'S STOMACH IMMEDIATELY by inducing vomiting. This can not be overemphasized, for it is the essence of the treatment and is often a lifesaving procedure. Prevent chilling by wrapping patient in blankets if necessary. Do not give alcohol in any form.

#### 4. Do Not Induce Vomiting If

1. Patient is in coma or unconscious
2. Patient is in convulsions
3. Patient has swallowed petroleum products (i.e., kerosene, gasoline, lighter fluid)
4. Patient has swallowed a corrosive poison (symptoms: severe pain, burning sensation in mouth and throat, vomiting)

#### CALL PHYSICIAN IMMEDIATELY

- (a) Acid and acid-like corrosives: sodium acid sulfate (toilet bowl cleaners), acetic acid (facials), sulfuric acid, nitric acid, oxalic acid, hydrofluoric acid (rust removers), iodine, silver nitrate (styptic pencil)
- (b) Alkali corrosives: sodium hydroxide—lye (drain cleaners), sodium carbonate (washing soda), ammonia water, sodium hypochlorite (household bleach)

---

From the Committee on Toxicology of the Council on Drugs of the American Medical Association, as published in the *Journal of the American Medical Association*, 1, October 1957, pages 655-658.

Reprints of this report may be obtained from Bernard E. Conley, Ph.D., Secretary, Committee on Toxicology, 4 M. A., 535 North Dearborn Street, Chicago 10, Ill.

If the patient can swallow after ingesting a corrosive poison the following substances (and amounts) may be given

For acids milk water or milk of magnesia (1 tablespoon to 1 cup of water)

For alkalis milk water any fruit juice or vinegar

For patient 15 years old—1 to 2 cups

For patient 5 years and older—up to 1 quart

**B Induce Vomiting When Non corrosive Substances Have Been Swallowed**

1 Give milk or water (for patient 15 years old—1 to 2 cups for patient over 5 years—up to 1 quart)

2 Induce vomiting by placing the blunt end of a spoon or your finger at the back of the patient's throat or by use of this emetic—2 tablespoons of salt in a glass of warm water

When retching and vomiting begin place patient face down with head lower than hips. This prevents vomitus from entering the lungs and causing further damage

**II Inhaled Poisons**

- 1 Carry patient (do not let him walk) to fresh air immediately
- 2 Open all doors and windows
- 3 Loosen all tight clothing
- 4 Apply artificial respiration if breathing has stopped or is irregular
- 5 Prevent chilling (wrap patient in blankets)
- 6 Keep patient as quiet as possible
- 7 If patient is convulsing keep him in bed in a semidark room avoid jarring or noise
- 8 Do not give alcohol in any form

**III Skin Contamination**

- 1 Drench skin with water (shower, hose faucet)
- 2 Apply stream of water on skin while removing clothing
- 3 Cleanse skin thoroughly with water rapidity in washing is most important in reducing extent of injury

**IV Eye Contamination**

- 1 Hold eyelids open wash eyes with gentle stream of running water immediately Delay of few seconds greatly increases extent of injury
- 2 Continue washing until physician arrives
- 3 Do not use chemicals they may increase extent of injury

**V Injected Poisons (scorpion and snake bites)**

- 1 Make patient lie down as soon as possible
- 2 Do not give alcohol in any form
- 3 Apply tourniquet above injection site (e.g., between arm or leg and heart) The pulse in vessels below the tourniquet should

not disappear nor should the tourniquet produce a throbbing sensation Tourniquet should be loosened for 1 minute every 15 minutes

4 Apply ice pack to the site of the bite

5 Carry patient to physician or hospital DO NOT LET HIM TALK

#### V1 Chemical Burns

1 Wash with large quantities of running water (except those caused by phosphorus)

2 Immediately cover with loosely applied clean cloth

3 Avoid use of ointments greases powders and other drugs in first aid treatment of burns

4 Treat shock by keeping patient flat keeping him warm and reassuring him until arrival of physician

#### MEASURES TO PREVENT POISONING ACCIDENTS

A Keep all drugs poisonous substances and household chemicals out of the reach of children

B Do not store nonedible products on shelves used for storing food

C Keep all poisonous substances in their original containers do not transfer to unlabeled containers

D When medicines are discarded destroy them Do not throw them where they might be reached by children or pets

E When giving flavored and/or brightly colored medicine to children *always* refer to it as medicine—*never* as candy

F Do not take or give medicine in the dark

G READ LABELS before using chemical products

---

#### HOW TO OBSERVE LIKE SHERLOCK HOLMES

A physician cannot afford mental pigeonholing Patients smell our moral pigeonholing or prejudice of any kind Still the physician should not accept all that is related as if he had blinkers He should watch for chronologic gaps inconsistencies and possible concealment of what may be important information He should listen carefully and critically and observe the patient as he tells his story how he carries himself how he speaks how he uses his hands Much information may be secured from observation alone During an interview the physician should be as observant as Sherlock Holmes "

# PERINATAL MORTALITY ASSOCIATED WITH CESAREAN SECTION

DANIEL C. GOOD *Lieutenant MC USA*  
WILLIAM S. BAKER, Jr. *Captain MC US*

THE OBSTETRIC literature is replete with reports from several centers concerning the trend of cesarean section in recent years.<sup>1-3</sup> The technique of the operation and an account of its development throughout the years was ably presented by Young.<sup>4</sup> Emphasis has been placed on the need for a decrease in fetal and neonatal mortality resultant from traumatic vaginal deliveries, and a change in indications for cesarean section to attain that end has been suggested by DeSopo.<sup>5</sup> To further decrease infant wastage Kallreider<sup>6</sup> advocated a trial of labor in all dystocia cases with vertex presenting where no history of previous cesarean section is present. Delivery is carried out by cesarean section if vaginal delivery proves to be impossible. Landesmann<sup>7</sup> has pointed out the minimum risk to the fetus when delivered by section following an unsuccessful trial of labor as opposed to the potential hazard of repeat section producing an increased infant mortality incidence due to inaccurate estimations of fetal size and to rupture of the uterus. With the advent of antibiotics infection has been adequately controlled, and better transfusion techniques and well stocked blood banks appear to be the answer to the hazard of sudden blood loss or hemorrhage. Despite all of these improvements in modern obstetric practice there still is reported from most of our larger centers a definitely greater perinatal loss following delivery by cesarean section over the vaginal route but paradoxically a definite decrease in maternal mortality. In an effort to uncover some of the reasons for the apparent increase in perinatal mortality following cesarean section a study was carried out on all infant deaths associated with cesarean sections performed at this hospital during the period 1 April 1951 through 31 December 1956. Particular attention was directed to (1) the indication for section, (2) the type of anesthesia and agent used, (3) the stage of gestation at time of operative interference, and (4) the fetal weights in so far as these data had any bearing on the resultant

perinatal mortality. The facts uncovered and the conclusions arrived at during this study provide the basis for this report.

### METHOD AND MATERIAL

During the period 1 April 1951 through 31 December 1956, 25,667 patients were delivered at this hospital, and of these 556 (2.2 per cent) were by cesarean section. This is about one half the accumulated cesarean section rate of 4.02 per cent as reported from published literature by Schneider.<sup>1</sup> It has been the policy in this institution to individualize the indications for cesarean section in each case. The majority of women who were previously operated on in another hospital or by a physician unknown to our staff are usually delivered again by the abdominal route, but "once a section, always a section," is not a hard and fast rule in our hospital. Previous cesarean section was the indication for operation in only 51.7 per cent of the cases.

During the period under study, there were 43 infant deaths associated with 42 cesarean sections for an incidence of 7.72 per cent. An analysis of the indications for cesarean section as noted in table 1 will reveal that for 21 infants the cesarean operation was not the factor causing death.

The indications for performing the operations and the resultant fetal mortality are listed in table 2. All infant deaths are attributed to one indication only and thereby do not adversely affect the statistics. It is to be noted that uterine inertia *per se* was not considered as an indication, however, after reviewing the charts it was evident there may have been some sections performed for inertia and classified as fetal pelvic disproportion.

A comparison of our cesarean section fetal mortality with the national figures as reported by Schneider is contained in table 3. It will be noted our overall incidence of fetal wastage is higher than the national average but compares very favorably when computed annually except for the years 1953 and 1954, and no apparent reason for this is readily evident.

An analysis of all fetal deaths during the period under study is presented in table 4. Here a comparison is made with the annual fetal mortality occurring in this hospital from any cause and that associated with cesarean section. In every instance it will be noted that cesarean section was associated with the greater infant mortality.

The type of anesthesia employed and the agent used in each case in the study is found in table 5. It will be evident that over 50 per cent of the patients had spinal anesthesia and the next largest group received inhalation anesthesia using cyclopropane alone or in combination with other agents. The possible adverse effect of cyclopropane on 12 infants in the study will require further analysis.

TABLE 1 Data on fetal deaths associated with cesarean section 1951 to 1956

## DISCUSSION

With the increasing safety of the cesarean section operation from the maternal point of view, nationally there has been a steady increase in its use in complicated cases. But all too often abdominal delivery has not resulted in a viable baby. Undoubtedly the indications for the cesarean operation have materially increased the fetal mortality in certain instances.

However, there are a considerable number of infants lost simply because of poor timing, the operation being performed either too early or too late. Of the 556 cesarean sections performed during the period under investigation, only 513 infants survived the neonatal period, making the fetal loss 7.72 per cent, while the gross incidence of fetal loss for all deliveries was 2.81 per cent during the same period at this hospital.

A study of table 1 will reveal the individual cause of death of each infant delivered by cesarean section in the study. Over half of the total infants expiring after section weighed less than 5 pounds. Abruptio placentae, diabetes mellitus, and placenta previa in that order accounted for a total of 19 infants' deaths. This is in accord with other reported series.<sup>4, 5</sup> Eleven infants died incident to repeat cesarean section and, of these, six were under 6 pounds in weight. This bears witness to the common error of operating before roentgenographic evidence of maturity is demonstrable in the infant. Since July 1954 a more careful appraisal of fetal age has been attempted in all cases prior to carrying out elective cesarean section. Five infants died following repeat cesarean section during this period, but only one infant died as a result of prematurity.

Perhaps one of the reasons for the noticeable reduction in fetal mortality during this period was the initiation of the policy of carrying certain preclampsic patients closer to term with the aid of antihypertensives and not resorting to immediate induction or surgical delivery without giving due consideration to the state of viability of the fetus. Also more emphasis has been placed on the use of roentgenography as an aid in determining fetal age as described by Adams.<sup>7</sup>

An analysis of the type of anesthesia and agent used in respect to the resultant fetal mortality revealed certain interesting facts. Two of 11 repeat sections had cyclopropane anesthesia, and both infants died in the neonatal period. One was term and the other premature. Four patients with abruptio placentae and three with placenta previa received cyclopropane anesthesia. Three stillbirths and one neonatal death resulted in the abruptio placentae group, and three neonatal deaths in the placenta previa group. One section for placenta previa was performed in the case of a twin pregnancy at 33 weeks of gestation. Certainly in view of several studies<sup>8-12</sup> on the adverse effect of general anesthesia, and cyclopropane in particular, on the oxygen carrying capacity and oxygen-utilization rate in the infants' circulation it seems reasonable to conclude that the fetal outcome in the aforementioned cases might have been different if local infiltration anesthesia had been used.

A comparison of the fetal mortality following cesarean section to that following vaginal delivery is, at best, difficult and inaccurate because the two groups of patients are categorically

different. Certain patients developing specific obstetric complications in the last trimester are likely to be delivered by cesarean section, however, these same complications probably would place the infants in jeopardy and lead to an increased fetal loss if they were delivered vaginally. Perhaps even more would have died if they had all been delivered vaginally. It would be of considerable interest to know the actual number of infant lives saved by the cesarean operation, but this can only be estimated.

### SUMMARY AND CONCLUSIONS

In a study of all infant deaths associated with cesarean sections performed at a naval hospital during the period 1 April 1951 through 31 December 1956, particular emphasis was placed on the stage of gestation, type of anesthetic and agent used, fetal weight, and indication for section at the time of operation as possible causative factors in the production of increased fetal wastage.

While the maternal mortality rate following cesarean section has been reduced to less than 1 per cent in most institutions, this study reveals that at this hospital the fetal loss following cesarean section during the period studied is about 7.72 per cent, well more than twice the fetal mortality following vaginal delivery. Further analysis revealed that over half of the infants lost following operation weighed less than 5 pounds regardless of the indication for surgery.

Exceptional care must be taken in choosing cases for cesarean section. Every effort should be made to avoid prematurity, and in this respect the fetal size and gestational age should be paramount in deciding the time an elective cesarean section is to be performed. The choice of anesthesia for a given indication is also considered extremely important to the fetal outcome.<sup>12</sup> Inhalation anesthesia using cyclopropane or other gaseous depressants should not be utilized in any instance where the fetus has already been precipitated into an hypoxic state.<sup>8-12</sup> Conservative management of placenta previa is recommended as a means of decreasing the incidence of prematurity with its resultant high perinatal mortality in cases that eventually are delivered by cesarean section. It also is urged that a reasonable effort be made to carry certain severe preeclampsia patients closer to term with the aid of antihypertensives, as an additional means of decreasing fetal wastage in cases requiring cesarean section for delivery.

### POLIOMYELITIS VACCINE AND IMMUNITY

"The amount of virus antigen injected is the principal determinant of the intensity of the immune response. This is reflected in the level of antibody induced and/or in the degree of immunologic hyperreactivity effected. Although antibody at demonstrable levels tends to persist for long periods it has also been observed that immunologic hyperreactivity continues even in those cases in which antibody has declined to nonmeasurable levels. The indications are that immunity to paralysis is mediated not only through existing antibody in the circulating blood but through the mechanism of immunologic hyperreactivity that calls forth antibody sufficiently rapidly after exposure to intercept invasion of the central nervous system even though pharyngeal or intestinal infection may have occurred."

# POTABLE WATER ON SUBMARINES

ARTHUR D JAMES *Lieutenant MC USN*

WARREN R SANBORN *Lieutenant (junior grade) MSC USN*

**C**ONTAMINATION of potable water with sewage, polluted water, or other nonpotable liquid presents a perennial hazard in public health. This is particularly so aboard a ship, and is acutely true within a submarine. Mount and Floyd<sup>1</sup> reported an outbreak of 326 cases of *Shigella flexneri* III aboard a cruiser, centering around a cross connection between potable water and salt water systems in a dishwashing machine. Salt water outlets in food service spaces have since been ordered out by regulation. Cheever<sup>2</sup> reported the survival of shigella in sea water for as long as 76 hours, emphasizing the danger of contamination of equipment by harbor water. While the purpose of this article is to point up sources of trouble in the potable water supply of submarines and to suggest possible methods of correction, many useful parallels may be drawn between problems of submarines and those of surface vessels and shore installations.

A study of the potable water systems of submarines in a typical submarine squadron was initiated in 1955 as a result of finding contaminated water in potable water tanks during routine quarterly checks. In an effort to determine all possible causes for this contamination, procedures and installations were discovered that represent potential hazards in all submarine squadrons.

## MATERIALS AND METHODS

The study concerned the following salient features: (1) water sources; (2) means of transfer; (3) water in tanks; (4) tank arrangements; (5) venting systems; (6) possible cross connections with nonpotable systems; (7) laboratory studies; and (8) malfunction reports. Diagrams and photographs were made to illustrate possible cross connections, improper venting arrangements and potable water hose stowage and certain water sanitation deficiencies.

A concentrated survey of the potable water tanks aboard a representative group of submarines was undertaken in an attempt

December 1957

## POTABLE WATER ON SUBMARINES

1793

to correlate nonpotable water with the deficiencies mentioned above. Standard methods for total bacterial count and coliform counts were employed. The same methods were used to study the water hoses, in which case samples of water were obtained from the hose as it first came through and after specified periods of time.

### RESULTS

The submarines were divided according to building yard into two major groups. Those from one yard had 22 of 254 tanks (8.7 per cent) positive for coliform organisms over a five-month test period. In the other group only 2 of 107 tanks (1.9 per cent) were positive.

The following deficiencies were noted in the potable water systems, equipment, and handling procedures<sup>1-7</sup> aboard the submarines studied:

**Inadequate Air Breaks in Vents From Potable Water Tanks.** The vents on some tanks on all types of submarines had inadequate air breaks. The air break is essential to prevent the back flow of liquid or spray into the potable water system (figs. 1 and 2).

**Common Bulkheads Between Potable and Nonpotable Liquid Tanks.** The number 1 potable water tanks on all submarines studied had a common pressure bulkhead with sanitary tank number 1. On some submarines the number 2 sanitary tank adjoined number 4 potable water tank.

**Common Bulkhead With Sea Water.** All potable water tanks had a common bulkhead (the pressure hull) with nonpotable liquid—the water in which the submarine was floating. This is a major discrepancy common to many other types of vessels.

**Scuttle Butts Constructed So That the Drain Line Enclosed the Inlet Line and Fittings.** Several submarines were found with types of scuttle butts (drinking fountains) which allowed this possibility of cross connection between potable and nonpotable systems.

**Direct Connections Between Potable Water Systems and Sanitary Systems.** While it was recognized that due to the inherent complexity of the operating systems of a submarine almost any type of cross connection between systems was possible, consideration was given only to the more probable causes of contamination. The scuttle butt mentioned above was one, the other was a drain directly to sanitary tank number 2 from the hot water tank in the galley of one group of submarines. This was evident on all blueprints, but in most instances it had been capped off.

Figure 1 Proper venting of potable water tanks aboard submarines.

Figure 2 Improper venting of potable water tanks of submarines.

**Access Hatch in the Top of the Potable Water Tank Forming Part of a Deck** In many submarines of both groups this deficiency occurred however in most cases the hatch was well sealed and protected by a false cover. The results of laboratory tests for

contamination were inconclusive. Nevertheless, a serious hazard was discovered on one type of one group of boats. Potable water tank number 2 lay alongside potable water tank number 3, and the access hatch to the potable water tank was in the lower deck. The contents of the sanitary tank under certain dry conditions backed up into the shower, creating a serious hazard by covering the potable water tank hatch with sewage resulting in possible back flow or aerosol through the water tank hatch (fig. 3).

Figure 3 Vent for potable water tank number 4 and access hatch to tank in crew's shower

**Improper Stowage of Water Hoses** Stowage of water hoses varied greatly. Some hoses were found in the relatively clean environment of dry stores. Others were in the well in the forward torpedo room. Still others were stowed topside in various places exposed to weather and spray. None were capped, and few were clean (figs. 4-6).

**Inadequate Flushing of Water Hoses Before Use** Many times it was found that persons connecting water hoses did not flush them adequately, if at all, before filling the tanks. It was found that flushing for 2-3 minutes was required to clean the hoses sufficiently to obtain a minimal bacterial count (fig. 7).

#### DISCUSSION

Certain of the inadequacies in potable water systems and water handling aboard submarines were of a major nature. Why did the submarines from one shipyard have a higher percentage of contamination than those from another shipyard? The significance of this situation and the reasons for it called for further, more specialized study. Tank placement in opposition to Public Health standards certainly deserves investigation as to the pros and cons of this design feature. Access to tanks is another major design feature that warrants examination as to feasible methods of change in certain instances.

The important considerations of the moment, however, are not these major decisions, but are the actions that can be taken immediately by ship's personnel to improve the potable water

Figure 7 Effect of flushing time on median total bacterial counts per ml sample on six water hoses.

supply and protect the crew's health. The air break on the vents to the potable water tanks can be made adequate with a minimum of pipe fitting ability. The requirement is that the air break be between the opening of the vent and the top edge of the funnel or trough below it must be twice the diameter of the vent line. Therefore a 1½ inch diameter vent pipe should have 3 inches between it and the drain below it. A simple shortening or lengthening of one or two pipes can remedy this situation easily. It was discovered during the study that in many instances an inadequate air break had resulted from improper reinstallation after some ship repair or alteration.

Most of the scuttle butts aboard submarines were of a satisfactory type, but a few were of the improper type. Installation of a free draining model would be a simple and inexpensive matter.

Hose stowage care and handling is an important problem. Hoses should be kept clean at all times and periodically disinfected with chlorine solution. The frequency of chlorination is determined by usage and accidental contamination. Whenever there is question about the sanitation of a hose, chlorinate it.

otherwise, in normal usage chlorine water should be added at least once every three months. Keep it in a bottle with the ends when not in use. Water hoses are used by crews at the harbor water whether they are capped or not. If such as this occurs, disinfect the hose with chlorine solution before it is used. Flush the potable water hose before use. Three minutes flushing is adequate under normal conditions.

Store potable water hoses, capped, in a clean dry place. Store them topside. Submarines are crowded, but space for a set of water hoses can be found. When in a major navy port find out if specialized workers are designated to make water connections for the ship. Use them, even if it requires a short wait.

Direct connections between potable and nonpotable systems such as those mentioned above should be determined and remedied. This is a quick job for navy auxiliaryman. Access hatches to potable water tanks should be inspected periodically for tightness and should be cleaned of any debris that has collected on them.

Finally, consider testing and chlorinating the water that goes into the potable water tanks. Nearly 100 per cent of the time the water obtained from an approved source in the continental limits of the United States is satisfactory when it gets to the ship. These studies have shown, however, that there are many ways the water can become contaminated after this point. The percentage of contaminated tanks discovered in this investigation points up the necessity for bacteriologic testing of the water in the tanks at least on a quarterly basis. Furthermore, normal chlorination of water never hurt anything, and it is a cheap safety factor. From unknown continental United States sources and all foreign sources chlorinate to at least 2.0 parts per million residual chlorine after contact time of 30 minutes.

Water borne disease can disable a submarine or seriously impair its fighting readiness. The same applies to ships and shore installations. The discrepancies and frequency of contamination observed, therefore, make it mandatory to correct all deficiencies in equipment and to handle potable water properly.

#### SUMMARY

Study of the potable water systems of submarines in a typical squadron disclosed discrepancies both in equipment and in procedures. Positive tests for coliform organisms were obtained from 8.7 per cent of 254 tanks in submarines from one shipyard but from only 1.9 per cent of 107 tanks in submarines from another shipyard, suggesting a relation to type of construction and

nature of equipment. Of 8 potential sources of contamination observed, 6 had to do with equipment or construction and 2 with procedure. The results indicate need for (1) emphasis on proper handling procedures, (2) a regular check of potable water tanks for contamination, and (3) a more complete and detailed study of causes of contamination of potable water tanks aboard submarines.

#### RESPONSIBILITY OF AUTHORSHIP

Publication of favorable results carries the moral obligation of immediate rectification or disavowal if the recommendations later prove to be of little or no value. If this is not done, many physicians attempting conscientiously to keep up with the latest developments in medicine may continue to follow the views in the original paper long after its author or others have decided that the concept has no merit. This is particularly true among physicians out in the grass roots who rely more on the journals than do their city cousins and who, with reason, are greatly influenced by optimistic reports coming out of the large research institutions.

## Clinicopathologic Conference

U S Air Force Hospital, Parks Air Force Base, Calif •

### Fever, Convulsions, Coma

**Summary of Clinical History** This 2½-year old, white female child was admitted to this hospital after having been ill with a respiratory infection for over one week. Seven days, and again five days prior to admission, she had been given penicillin by injection. One day before admission she had been given vitamin B for vomiting. Therapy with Aureomycin Hydrochloride (brand of chlortetracycline hydrochloride) was started at that time.

During the 24 hours before admission she had a high temperature and had been delirious. She had complained of pain in the right arm a few days before admission.

**Physical Examination** On admission her rectal temperature was 105°F. She appeared acutely ill and had a "glassy stare." The right eardrum was dull and bulging with exudate behind it. The left ear was normal. The throat was injected. There were fine rales over both bases, more marked on the left. No dullness was noted. The heart beat was rapid (110 per min) but regular. No murmurs were heard. The abdomen, genitalia, and extremities were normal.

**Laboratory Studies** On admission the red blood cells numbered 4,560,000 per  $\mu$ l and the hemoglobin was 12.5 grams per 100 ml. The white blood cells were 6,550 per  $\mu$ l with 4 per cent meta-

---

Col John W Lindesty, USAF (MC), Commander. From the Laboratory Service.  
Maj Robert E Pierce USAF (MC) Chief.

myelocytes, 17 per cent band forms, 61 per cent neutrophils, 15 per cent lymphocytes, and 3 per cent monocytes. The urine contained a few epithelial cells.

**Course in Hospital** The following medications were ordered on admission. Aurilgan ear drops in both ears, four times daily. 0.25 per cent solution of Neo-synephrine hydrochloride (brand of phenylephrine hydrochloride) as nose drops, four times daily, steam inhalations. Chloromycetin Palmitate (brand of chloramphenicol palmitate), Linctus Compound as needed for cough. Diet, as tolerated, with forced fluid intake, sponge baths and 200 mg of aspirin as needed for fever of 103.5°F or above, and 0.6 ml of ABDEC (multivitamin preparation) twice daily.

The lowest temperature the day of admission was 101.8°F. It was 103 to 104.6°F for most of the day and remained elevated the following day. A roentgenogram of the chest revealed bilateral bronchopneumonia. White blood cells now numbered 4,650 per  $\mu$ l, with 16 per cent band forms, 33 per cent neutrophils, 40 per cent lymphocytes, and 9 per cent monocytes. Brucella, *Salmonella typhosa*, *Salmonella paratyphosa*, and cold agglutination tests were negative. Stool cultures revealed no pathogenic organisms.

The day after admission the patient had a convulsion which lasted 3 minutes. An enema of 8 ml of paraldehyde in mineral oil was given, part of it being retained. Following sponge baths, administration of aspirin, and a small enema, her temperature fell to 99.8°F.

At 0210 on the second hospital day the child had a convulsion which persisted for over one hour. Paraldehyde was given by rectum but was expelled with a green, liquid stool. At 0240 and again at 0255, 200 mg of Luminal Sodium (brand of phenobarbital sodium) was given. Her temperature at 0255 was 106.4°F. The convulsions continued and ether was given by mask with only temporary relief. At 0345 a lumbar puncture was performed, after which the convulsion ceased although the patient remained unconscious. The spinal fluid was clear and contained 1 lymphocyte per  $\mu$ l. The spinal fluid sugar was 113 mg per 100 ml, total protein, 24 mg per 100 ml. Chlorides, 620 mg per 100 ml, and culture, negative. One gram of Gantrisin (brand of sulfisoxazole) in 100 ml of water, 5 per cent dextrose in water, and 130 ml of blood were given through a venous cutdown.

Convulsive movements persisted intermittently until noon. At 1400 the patient's color was poor and her pulse was weak. Suction was applied and a mucus plug was removed. The child's color improved following this. Her temperature was 98.8°F and remained below 100°F the remainder of the day. Gantrisin was given twice daily, and 7.5 ml of blood and 40 units of Aethar gel (brand of corticotropin) were given.

The patient's condition remained about the same on the 11th hospital day. The highest temperature was 102°F (38.9°C). Previous medications were continued, 100 ml of blood was given and intramuscular injections of 250 mg of Chloroquine were given twice daily. On this day her face was edematous.

She improved slowly over the next few days. On the fifth hospital day Vinco formula was begun by tube. The child's temperature ranged from 98.6° to 100°F. She remained comatose with occasional stirring and groaning. Her stools were meconium-like. On the sixth hospital day the liver was palpable 4 fingers breadth below the right costal margin. There was roentgenographic evidence still of bilateral bronchopneumonia. There was no cardiac enlargement. Urine was checked daily for sulf crystals, but none was found.

On the seventh hospital day the liver edge was below the umbilicus. The patient opened her eyes and moved but remained on the verge of consciousness. Her temperature remained below 100°F. One half unit of plasma was given every 12 hours. Her temperature spiked to 106°F on the ninth day, but dropped rapidly. The liver gradually decreased in size. She vomited small amounts of what apparently was old blood. Her temperature then began climbing to 105°F. On the eleventh day Gnttrin was discontinued and 250 mg of Terramycin Hydrochloride (brand of oxytetracycline hydrochloride) was given every 12 hours. She remained semicomatose. Stools remained meconium-like and rales continued in the lungs. The white blood cell count remained low, with a high of 11,100 per  $\mu$ l on the eleventh day, with 12 per cent band forms, 58 per cent neutrophils, 28 per cent lymphocytes, and 2 per cent monocytes. The child appeared spastic. Throat culture taken on the twelfth day revealed "Streptococcus"

Early on the sixteenth day the patient stopped breathing but started again with artificial respiration. The lungs contained rhonchi. She became stuporous, and oxygen was necessary. A lumbar puncture on that day disclosed clear colorless fluid with an initial pressure of 224 mm of water. About 15 ml of fluid was removed, following which the pressure was 90 mm of water. The spinal fluid contained 1 lymphocyte, the sugar was 93 mg per 100 ml, total protein, 18 mg per 100 ml, chlorides, 560 mg per 100 ml, and the Pandy test was negative. The patient was more edematous and her abdomen was distended. Her respirations became weaker and shallow, and cyanosis increased. The patient died on the seventeenth hospital day.

## DISCUSSION

**Doctor Barkin** This case is that of a 2½-year-old female child who had a respiratory infection for over a week and was admitted with a high fever. She had been delirious for approximately 24 hours before admission. A week before admission she had been given two injections of penicillin which had very little effect on the fever. She also vomited on the day before admission and had some pain in her right arm. There is no other mention of this symptom and it was not severe. Aureomycin was started and apparently discontinued the same day.

When she was admitted she had a temperature of 105°F and appeared acutely ill. This indicates to me a bacterial infection. Many children that we see in the clinic up to 3 or 4 years of age may have a temperature of 103° to 104°F, and there is one child I am thinking of who had a temperature of 107° for a week with nothing more than we could find than an upper respiratory tract infection and a normal white blood cell count and differential. When she came in she would run up and down the hall and appear fine. This is a big differential point with children. If they look fine it is usually a viral infection. If they appear acutely ill it is usually bacterial.

It was described that she was delirious. This is unusual even with a 105°F temperature unless there has been some evidence of convulsive-like movements so this is a pretty sick child.

The right eardrum was dull and bulging and had an exudate behind it. With a purulent otitis the organisms are usually hemolytic streptococci, pneumococci or staphylococci, and should she have had an ear infection when she was given the penicillin you would have expected some improvement of the ear. If she had a purulent infection for a week you would have expected the bulging drum to have perforated. So this apparently was a real acute otitis. Usually if some condition is present such as rhinitis or pharyngitis enough to give an infection of one ear and if it has been going on for several days, both ears would be involved. Here the left ear was reported as normal.

She had bronchopneumonia. Her heart rate was 110 per minute. That is a normal heart rate for a child of 2½ years with no fever. With a temperature of 105° one would expect a heart rate of 160 to 170. So this is a bradycardia.

The extremities were found to be normal and there was no tenderness of the right arm although she had complained of pain in it several days before. Blood examination showed 12.5 grams of hemoglobin. This is probably still more evidence that this is an acute affair.

She was apparently well up until a week prior to admission and the white blood cell count was 6550 per  $\mu$ l although there was a

definite shift to the left in the differential. The urine was essentially normal.

Auralgan drops were put in both ears (apparently both ears were hurting the child, even though the left ear was described as normal). She had a cold which is the primer of most ear infections. Chloromycetin Palmitate was given. The antibiotic the physician is quite varied here with Aureomycin started the day before. Sponge baths and aspirin were given to lower the temperature.

The temperature on the day of arrival varied from 101.8° to 104.6°F and it remained elevated the following day. Bronchopneumonia was confirmed by roentgenography. The repeat count still showed a low white count and there was an increase in lymphocytes and in monocytes.

A cold agglutination test was negative. Usually it is the second week before cold agglutinations become positive. Brucellosis was considered. This disease is not as chronic as brucella infection. The child was apparently sick throughout the day, instead of appearing weak in the morning and better in the afternoon. An enlargement of the liver and spleen may occur in brucellosis, and there may be an encephalitis, which is the type of picture that the child had later on. Brucella agglutination usually becomes positive after about 10 days. So we are at the point here where it may or may not be positive.

*Salmonella typhosa* and *paratyphosa*—I think there are a number of things which go along with typhoid fever and I'll discuss this condition a little later. The agglutinations, according to the curve, are approximately 30 per cent positive at the time when the blood was drawn from this patient. Of course paratyphoid can produce a similar picture, although it is rather rare in the States.

The temperature rose to 105°F and the child developed a convulsion. Apparently it wasn't until the temperature was lowered to 99.8° that the convulsion stopped, and this appears to have been a febrile convulsion. Paraldehyde was given rectally, and it was noted that the second time paraldehyde was given on the next morning, there was a green, liquid stool. This was probably a result of the irritation of the rectum caused by the paraldehyde.

The child began having convulsions the following morning, the second hospital day. At that time the temperature was up to 106.4°. Luminal, 200 mg, was given in a 15 minute period. Ether by mask didn't help. It wasn't until a lumbar puncture was done that the convulsions ceased. I wonder if the temperature also went down at the time the convulsions ceased? If the lumbar puncture relieved it, you would think of some increase in intracranial pressure. It is very difficult in a 2½-year-old child to measure a spinal fluid pressure and I sympathize fully with the physician who was doing this. If the fever had gone down the convulsions may have topped because of this.

and instead of the lumbar puncture. The spinal fluid appeared clear and the findings in it were perfectly normal.

At this time Cantisin was given as well as 130 ml of blood, which was a supportive measure. The child had a hemoglobin of 12.5 grams per 100 ml and this would raise it a little more than a gram. Twenty milliliters of blood per kilogram of body weight increases the hemoglobin 3 grams.

The convulsive movements persisted. The child was aspirated and a plug removed. It was apparently thought that the child was in early shock and Aetheral gel was started. Again a small amount of blood was given for supportive treatment. As to how severe the convulsive movements were on the morning of the second day, it is a little hard to tell. If the child was in status for that hour and a half perhaps there was serious brain damage but if this was a matter of individual convulsions with twitchings that continued for that period of time one would not expect the child to suffer any degree of brain damage. One out of 14 children under the age of three, have convulsions with fever and many of them continue for an hour or more yet it is unusual to have brain damage.

Cantisin having been started now Chloromycetin was started with a dosage of probably about 50 mg per kilogram and some more blood was given.

Her face was edematous after two days of intravenous fluid therapy. The most common difficulty that would cause a child to become edematous is too much salt in the fluid which is given. In order to keep the cutdown open you must keep a flow of at least 6 drops per minute and that would amount to about 360 ml of fluid. She had previously received 100 ml of blood and this alone would give the amount of salt for her daily requirements. About a gram a day is all the salt a 2-year-old child needs. An accumulation of salt from the other fluids was probably the reason for this sign. The urine was checked daily for sulfa crystals and I imagine that it was checked for albumin particularly since the patient was edematous.

Two days later it was noted that she had some meconium-like stools. She had convulsed several times and may have bitten her tongue or her lip and had enough bleeding there to give a tarry stool if this was a tarry stool. The other things that are less common would be a Meckel's diverticulum or the swallowing of a foreign body. Usually you would expect bright red blood with a Meckel's diverticulum but it can be dark. A duplication of the bowel which is usually present in the small intestine with bleeding from a marginal ulcer could give tarry stools. Of course an ulcer could also give tarry stools. If the paraldehyde had irritated the rectum you would expect any evidence of blood to be brighter. Bleeding from ulcers in the ileum in typhoid fever could produce tarry stools but it is a lot more uncommon in children than it is in adults.

The temperature was down on the fifth hospital day. In a condition like typhoid fever, which I will discuss later, the temperature is usually elevated for at least a two- to three week period.

On the following day the liver was suddenly noted to have gone down four fingersbreadth, which indicates heart failure. Roentgenograms showed evidence of bilateral bronchopneumonia. There was no evidence of cardiac enlargement. This is hard to tell in a child and it is hard to evaluate that statement. As to the cause of the heart failure, the child still had the cutdown and an excessive amount of fluids can throw a child into heart failure. I have seen five children thrown into heart failure where it was obviously from fluids. They were usually six months old or younger and 500 ml of fluid in an hour could throw a perfectly normal six-month old infant into heart failure. But here is a child of 2½ years with kidneys in good condition. Could there have been a congenital heart disease? There is no evidence of any murmur and no cardiac enlargement so you would tend to discount those conditions with a large heart and no murmurs such as an aberrant left coronary artery or fibroelastosis. Could this be due to a myocarditis from an infectious process? The pneumonitis could have been quite severe, and typhoid fever could cause a myocarditis.

The following day the temperature spiked to 106°F. This is now about five days during which the child was apparently afebrile, and the heart failure, which I believe the condition is, has subsided to some degree with the liver gradually decreasing in size. I wonder why there is no mention of digitalizing the child, or of oxygen or other therapy.

She then vomited small amounts of apparently old blood. Any blood swallowed during the convulsions five days before certainly would not be expected to remain in the stomach long. Again the possibility of a high ulceration is present. The temperature remained high. The Gantrisin which had been given for a week or more was discontinued and Terramycin was started.

The patient still remained comatose. This is a period of seven or eight days. One thinks now of a progressive central nervous system disease. Rales continued in the lungs. The white count was still low. A child of 2½ years of age is able to respond very well to infection and with a purulent infection you would expect the count to have been high. The child now appeared spastic. This would point to progressive central nervous system disease.

And now the "fly in the ointment" a yeastlike fungus appeared in a throat culture. There are a number of fungus diseases which affect the central nervous system. Torulosis is the most common, but there is also saccharomyces, oidium, coccidioidomycosis, blastomycosis, sporotrichosis and actinomycosis. The symptoms of these usually depend on whether or not a granulomatous process was formed to cause obstructive signs and symptoms, or whether different

portions of the brain are involved. The spinal fluid findings usually are those of a meningitis, particularly with torulosis with high protein, low sugar and increased cells. The symptoms are not usually those of an acute infection. There is usually no fever with torulosis but when there is it is usually only up to 101°F. So this doesn't appear to be a fungus condition.

The following day the patient stopped breathing, the lungs contained rhonchi and she apparently had pulmonary pathology. The lumbar puncture done that day showed an initial pressure of 224 mm of water. Here is a child who is stuporous so that would be an accurate pressure. The pressure is normal up to 200, this is a little above. Blood chemistry studies again were normal and only one lymphocyte was present. The patient was more edematous and her abdomen was distended. She had been given positive pressure oxygen which could account for the distension of the abdomen. Then she died of a respiratory condition.

The picture then is that of an encephalopathy. This can occur with glomerulonephritis but wouldn't be expected to have persisted this long and there would have been abnormal urinary findings. In a child in coma with diabetes the urine would have showed sugar. Lead encephalopathy is something that has to be considered in every child. A child at 2½ years is at the nibbling stage and may have nibbled some of the paint off of her father's shoes if he was a painter. With the respiratory infection the lead may have been mobilized out of the bones into the blood. But central nervous system findings in a child which are severe enough to cause death are usually pretty striking. Usually the pressure is markedly elevated and may be up as high as 900 mm of water and the protein also is markedly elevated. There is no evidence of this in two taps. Other encephalopathies may be toxic or hemorrhagic and caused by pneumonia, dysentery, typhoid fever, typhus, scarlet fever (occasionally) and brucella.

I should like to talk a little more on typhoid fever. This is a possibility in this child. It produces a demyelinating encephalopathy. The child became spastic and this may have been what produced a lot of the findings. The stools are not loose although in a series of 252 cases reported by Holt and McIntosh<sup>1</sup> only one half had diarrhea. Half were found to have rose spots. These are easy to miss. Only 30 per cent of agglutinations are positive at the time that this agglutination was obtained, and this well may have been one of the 70 per cent that aren't positive. You would have expected to find a positive stool culture. The leukopenia and lymphocytosis would go along with typhoid as would the bradycardia which was present. The meconium-like stool if this was evidence of ulceration would go with typhoid fever and the myocarditis may have been the cause of the heart failure.

As to the most probable diagnosis we must go back to the ear infection. Here was a bulging drum and you get a mastoiditis with an

ear of this type, just as you get a sinusitis with a cold. Thus, a brain abscess must be considered. The sugar, chlorides, and proteins are normal, the globulin should have been up, and the blood cell count also would be up.

Doctor Hensler: I think the possibility of trichinosis might be considered. The child complained of pain in the arm, also the apparent involvement of the gastrointestinal tract, and the myocarditis would go along with this. I don't think that this is a very likely diagnosis, however, but it is something to be considered.

Dr. Borkin's diagnoses:

- 1 Brain abscess
- 2 Typhoid fever

#### PATHOLOGIC FINDINGS

Doctor Pierce: At autopsy the patient was a well-developed, well-nourished, female child appearing of stated age. There was moderate edema of the face and slight pitting edema of the legs. Small amounts of clear brownish fluid were found in the peritoneal and pleural cavities.

The scalp and meninges were generally very edematous. The brain weighed 1,150 grams, and there was marked edema throughout. The gyri were flattened, with narrowing of the sulci. No pressure cone was present. No other changes were evident grossly.

The heart showed no gross changes. There were scattered small areas of hemorrhage beneath the visceral pleura. Both lungs were markedly edematous and congested. There was no gross evidence of consolidation or of a pneumonic process.

The spleen was congested. The liver extended three fingersbreadth below the right costal margin at the midclavicular line. The liver weighed 970 grams. The parenchyma was pale pink and the lobules were grossly very prominent. There was marked edema.

The gastrointestinal tract was essentially normal throughout. No mucosal changes were found in any area. There was no lymphadenopathy.

The kidneys appeared grossly swollen. The right kidney weighed 135 grams, the left weighed 140 grams. The capsules stripped easily, revealing swollen and pale cortical surfaces. Throughout the cortical and medullary portions of both kidneys were many small, white tuberclelike formations measuring from 1 to 1.5 mm in diameter. There was marked edema of both kidneys. The findings were grossly similar to renal tuberculosis. Frozen sections done immediately, however, revealed them to be pyogenic abscesses.

---

\*Maj. Nester M. Hensler, USAF (MC), Chief Pulmonary Disease Service.

Microscopic examination of the lungs showed a generalized edema. A few scattered alveoli contained neutrophils, but no significant pneumonic process was found.

Sections of the brain showed generalized edema. Scattered throughout the cerebrum were focal areas of necrosis with leukocytic infiltration (fig. 1). The ganglion cells in some areas showed early ballooning degeneration. A few perivascular hemorrhages were found.

Examination of sections of the myocardium showed a very few small scattered abscesses (fig. 2). No other significant changes were evident.

Microscopic sections of the liver showed the majority of the hepatic cells to contain globules of fat. The cells were swollen and the sinusoids compressed. Mitotic activity was evident. Much granular brown black pigment, similar to hemosiderin, was noted in the Kupffer cells. The findings in the liver were interpreted as marked fatty degeneration, probably on the basis of a toxic process. No abscesses were found. The gastrointestinal tract, pancreas, spleen, and adrenals were not remarkable on microscopic examination.

The kidneys on microscopic examination showed multiple focal areas of necrosis, some rather large, with large numbers of neutrophils present (fig. 3). A few of the glomeruli showed epithelial crescents.

Figure 1. Microabscess in cerebrum. (Hematoxylin-eosin stain,  $\times 50$ )

Figure 4 Renal abscess containing fungus. (Gomori stain,  $\times 50$ )

Figure 5 High-power view of fungus (Gomori stain  $\times 215$ )

cents. The tubular epithelium showed necrosis and areas of calcification.

During the microscopic examination of the cerebral and renal abscesses in the hematoxylin and eosin preparations, chains of large organisms resembling hyphae were noted. Special stains showed gram positive, yeastlike fungus forms, with both hyphae and spore forms present in large numbers in the abscesses (figs. 4 and 5). The organisms were identified as *Candida albicans*.

The findings of systemic moniliasis has been reported with increasing frequency over the past several years. The infection usually has been in cases of chronic debilitating illness, which was not the circumstance in this case. This child had been ill for only three weeks and at autopsy was still well nourished.

The use of broad spectrum antibiotics has more recently been implicated in such cases and some have been shown to stimulate the growth of monilia in vitro. This is presumed to be the basis of this case. The child undoubtedly, as we have heard, originally had a respiratory infection with bronchopneumonia and otitis. Following the onset of the disease she received a total of six different antibiotics. It is presumed that the organism gained entry via the gastrointestinal tract which had probably been pretty well rid of its normal bacterial flora by the antibiotics.

I think that this well may be taken as a warning to us against the excessive use of combinations of antibiotics over any period of time.

#### Pathologic diagnoses

- 1 *Candida* mycethemia with multiple renal, cerebral, and myocardial abscesses
- 2 Marked fatty degeneration of the liver

# RESUMPTION OF MILITARY DUTY AFTER TREATMENT FOR TUBERCULOSIS

JAMES A. WIER *Colonel MC USA*  
CARL W. TRIMPEL *Brigadier General MC USA*

PRIOR to the use of chemotherapy in the treatment of patients with pulmonary tuberculosis relapse rates for those treated with bed rest were usually high. In a study of military patients with minimal tuberculosis inducted into service during World War II Waring and Roper<sup>1</sup> showed that the relapse rates varied between 30 and 70 per cent depending on the status of the disease and the type of military duty performed. In patients with more advanced tuberculosis the rate of "cure" or attainment of inactive disease was lower and the breakdown rate in these patients was high even under sheltered conditions. This unfavorable prognosis made it difficult to return any patient treated for pulmonary tuberculosis to military duty in a reasonable period of time. Although in the past a few selected individuals with minimal tuberculosis and with pleural effusion had been treated in the military service and returned to duty the usual practice had been to recommend permanent retirement for any individual found to have active tuberculosis.

The successful use of chemotherapy and operative procedures in the management of tuberculosis in the past decade reversed this trend and gave support to the contention that patients with tuberculosis might be treated and eventually returned to duty within the military service.<sup>2</sup> It has been the experience at this hospital that the relapse rate for military patients treated to the inactive stage of disease prior to discharge from the hospital was no higher than 5 per cent. It also was noted that in patients with new disease and with less advanced pulmonary tuberculosis a recovery rate of 90 per cent or higher could be attained with the same low eventual relapse rate. The active tuberculosis case finding program in the Armed Forces made such favorable results possible.

---

From Fitzsimons Army Hospital, Denver, Colorado. Trimpele is now Commanding General of Valley Forge Army Hospital, Philadelphia.

Presented at the meeting of the Section on Military Medicine, Scientific Assembly of the American Medical Association, New York, N. Y., June 1957.

The policy of separating from service all personnel with tuberculosis resulted in the loss of well qualified military manpower. In October 1949 the 81st Congress passed Public Law No. 341 which provided for temporary retirement of military personnel from the Armed Forces who were temporarily disqualified for active duty by disability. This law enabled the military services to retire the tuberculous patient to civilian life for a period of time up to five years. At the conclusion of this time or at any intervening period the individual could be returned to military service when found to be physically qualified. A number of military personnel were restored to an active-duty status by this means. However it was noted that many well motivated career officers and men who were temporarily retired to civilian life refused to re enter military service on recovery and conclusion of temporary retirement. While on retirement many of these men found good jobs in civilian life which made it difficult for them to sever these connections and re enter military service although they were well motivated while in the service. This loss was most critical to the Armed Forces when highly trained specialists failed to return to active duty. The cost to the Government in training these individuals was high. It has been estimated, for example, that the cost of training a highly skilled pilot of military aircraft was at least several hundred thousand dollars, and of some enlisted specialists as high as 15 to 20 thousand dollars or more. This investment by the Government was completely lost if these individuals did not return to duty. These same men with specialty training are the ones who upon retirement were best able to get well paying positions as civilians.

In view of the excellent results of treatment with low relapse rates, it was deemed possible to treat many military patients to a stage of inactive disease and return them to a duty status with only temporary limitations of physical activity. For this reason, in 1951 this hospital was authorized to return selected military patients directly to active duty. Initially only selected career personnel were returned to duty, particularly those showing a good response to treatment and with minimal residuals of tuberculosis. These trained specialists with definite value to the military service were given the option of a disability discharge or restoration to duty after an appropriate period of convalescent leave. It was considered necessary to give patients such a choice to make certain that every individual returning to duty sincerely wished to do so. Without motivation for service it would have been extremely difficult to evaluate the number of patients qualified to remain on active duty over a period of time, as the diagnosis of tuberculosis incurred in line of duty entitled them by law to Army retirement pay or compensation from the Veterans Administration when processed by a Physical Evaluation Board. These patients were returned to restricted duty under the limi

tations provided by the Army physical profile regulations. The profile code number "P3" excluded strenuous physical exertion such as might be required in combat or field training. These patients were qualified for overseas duty however, and by and large performed the general type of duties required of other soldiers on all but the most arduous type of assignment. Through the period of years since 1950 good results were maintained and better results accomplished by surgical treatment and newer drugs administered over prolonged periods. The estimated tuberculosis relapse rate continued at about 5 per cent and thus more patients were allowed to return to duty including those who were admitted to the hospital with advanced tuberculous lesions.

### RESULTS

Follow up of tuberculosis patients returned to military duty since 1952 has been undertaken at this hospital. During the period of 1952-1955, 293 patients have been returned to duty, recent follow up reports have been obtained on 261 (96 per cent) of those (table 1). Of the 261 patients followed, 233 (83 per cent) are still on active duty (table 2). Some of these have now been on duty 5 years, while those discharged to duty in 1955 have been on duty less than 2 years. During this same period of time 47 of the former

158 patients were returned to duty in 1956 increasing the present number in this category to 451 to date.

patients have been separated from the service 41 of these for reasons other than physical disability. Eleven have shown worsening of their disease. One is on temporary retirement because of an apparent recurrence of active disease (table 3). Five patients have been retired permanently for physical disability, 3 of these for nontuberculous disability, 1 because of tuberculosis and 1 for reasons unknown. Six of the relapses have occurred in patients discharged to duty in 1952, 1 of those patients received temporary retirement and is now back on duty status, 4 have been recommended for return to duty and 1 is in the hospital being

treated for active tuberculosis. Of the six patients returned to duty in 1952 who suffered relapses only one received more than six months of chemotherapy. The recurrence of disease in a patient who was returned to duty in 1955 is actually a nontuberculous condition. This patient had a difficult course during the time of original hospitalization with both tuberculous and non

TABLE 2 Follow-up data on tuberculous patients who returned to duty

1955	9	9	0	0

tuberculous complications following surgical intervention. He was rooperated on for a bronchopleural cutaneous fistula which reopened while he was on a duty status. The lesion proved to be due to a resistant staphylococcus, with no evidence of tuberculosis found at the time of the operation. Because of this patient's past history, however, he received another course of antituberculous drugs, and is now on convalescent leave prior to returning to duty again.

One hundred and fifty eight patients were returned directly to duty in 1956, increasing the total number of individuals in this group to 451. The follow up period of these patients has been too short for evaluation in this report. It is pertinent to point

out however that this figure reveals the current trend to restore more and more tuberculous patients to a duty status following successful treatment

Those patients separated from the service for reasons other than disability are still being investigated to find out the actual cause for termination of duty. Most were separated for administrative reasons such as completion of 20 or 30 years of service or termination of term of enlistment. All patients being retired from the service after leaving this hospital are being investigated to find the actual cause of retirement. This has been completed in some as mentioned above, but in a few instances the exact cause for physical separation is not known

Of the patients placed on temporary retirement and discharged with inactive disease to their homes or those transferred to the Veterans Administration for further treatment most have made excellent recoveries. After a period of one or two years of inactive disease most of these patients have been recommended for return to active duty which drops them from the Army retirement rolls if restoration to service is not accepted by the patient. Of 1,900 who have been given temporary retirement from the military service, 1,532 have been recommended for return to duty, 339 are still on temporary retirement, and 29 have been given permanent retirement for tuberculous or nontuberculous conditions. The relapse rate in this group of temporarily retired servicemen is 2.3 per cent at this time (table 4)

## DISCUSSION

In view of the generally excellent results of treatment for tuberculosis with modern day therapy and with the low relapse rate that has been evident in patients receiving adequate chemotherapy, it is our belief that it is not wise or economical to arbitrarily separate career motivated military personnel from military service when diagnosed as tuberculous. Experience over a five year period demonstrates that the return of these military personnel

to duty with only minimal restriction of their physical activities is entirely feasible. Retention of these individuals on active duty for periods in excess of two years has been accomplished in 83 per cent, with most of the remainder being separated from the service for administrative reasons. The rate of relapse of tuberculosis is extremely low—4 per cent in those followed to date. This demonstrates conclusively that the policy of returning the treated tuberculous patient to duty is practicable and that the danger of contagion to other military personnel is negligible. If these former patients are carefully and adequately followed a relapse is not necessarily a serious condition because in most instances it will be noted early, permitting successful retreatment of their disease and possible return to duty again.

Precise final data on results of this program will not be possible until a complete follow up study of at least five years has been accomplished on all patients returned to duty, and until the exact disposition of those discharged from the service is determined. It is the policy at the present time to request that chest roentgenograms of all patients returned to duty be sent to this hospital once yearly for comparison with previous films. It is believed that if the patient is asymptomatic on a duty status and shows no change in the chest roentgenograms, this will give us the desired proof of good health and the best practical follow up study for large numbers of individuals. In most of the former patients it will be possible to secure the results of bacteriologic studies which have been accomplished. In those patients on whom we have records indicating they are on a duty status (96 per cent with follow up reports), we have received and reviewed chest roentgenograms on approximately one half at this time. This was initiated only recently and it is our intention to do this once yearly for five years of follow up study.

Tuberculous patients, in general, have accepted their reassignment to duty after recovery in good faith and have taken overseas assignment without complaint. With the present program of increasing ambulation in the treatment of tuberculosis, it is anticipated that a higher percentage of our patients will be returned to duty in the future. The patients are being given part time work during their hospitalization periods and everything is geared toward eventual return to duty. These patients should be better fitted for duty on their return to service, as the philosophy of successful rehabilitation is being advanced to them from the beginning of hospitalization. They are assured that they are still on a duty status and will go back to active duty as soon as possible, and that this is a temporary physical setback like a broken leg or any other temporary disability. This optimistic concept favors the continuance of a military career and reduces the desire for retirement for disability reasons.

## SUMMARY AND CONCLUSIONS

A program of returning military patients to duty after treatment for tuberculosis included two groups of patients, the first being those restored directly to duty after treatment and the second group being those returned to active service after a period of temporary retirement.

During the period of 1952 through 1955, 293 personnel have been returned directly to duty after the successful treatment for tuberculosis. Of these 233 are still performing military duty as revealed in the 2 to 5 year follow up study. The relapse rate in these patients has been extremely low. Of the 11 showing recurrence of the disease 6 were discharged from the hospital in 1952. Forty one patients have been separated from the service for other than physical disability reasons and five have been given permanent retirement.

The follow up study of 1,900 military patients temporarily retired because of tuberculosis between the years 1950 to 1955 reveals that 81 per cent were found fit for duty after an average of 1 to 2 years of separation from service, and that only 2.3 per cent showed reactivation of the disease. Of the 1,383 patients treated for pulmonary tuberculosis 39 (2.8 per cent) showed a worsening of their disease during the follow up period.

In this day of highly technical armament the medical services of the Armed Forces must make every effort to conserve skilled military personnel, including those recovering from tuberculosis. In this report it has been shown that 80 per cent or more of tuberculous patients discovered reasonably early by an active case finding program can be rendered fit for return to military duty by modern day treatment. These results support the contention that it is feasible to treat most of the well motivated career military personnel to the stage of inactive disease and return them to useful service soon thereafter or following a short period of temporary retirement. The monetary savings to our Government by this program is very significant but more important members of the Armed Forces who develop tuberculosis in service can now almost certainly recover their health and live a normal life with little danger of recurrence of this chronic disabling disease.

# PSYCHIATRIC SCREENING OF COMBAT PILOTS CORRECTION OF THE RECORD

SAUL B SELLS *Pb D*  
DAVID A TRITES *Pb D*

**T**HE PURPOSE of this article is to correct factual errors and erroneous conclusions in an article by Sparks and Niess<sup>1</sup> which appeared in the June 1956 issue of this *Journal*. That article cited data from an unpublished report of the present authors<sup>2</sup> which has since been published.<sup>3</sup> Inasmuch as the conclusions stated by Sparks and Niess are based principally on our data, which are incorrectly reported and interpreted, and as we had no opportunity prior to publication, to read their paper, it is necessary to set the record straight. Their article has already been cited by two other authors,<sup>4, 5</sup> to our knowledge, who appear to have accepted their conclusions.

The particular conclusions and interpretations stated by Sparks and Niess, which are unsupported when the correct facts are used, are as follows:

1 That "psychiatric screening for combat duties, based on training level group psychologic test data and/or clinical appraisal as used in the project discussed here" appears as yet unable either to screen out the failures or to identify the successes in combat flying."

In their discussion of results, they stated "The results seem to indicate that the psychologists at training level understood neither the nature of combat stress and its effect on personality nor the psychic variables which constitute probable success or failure. The fact that their estimates were in significant disagreement with the estimates of both combat peer superiors and combat psychologists indicates that the hypotheses on which their predictions were made were *significantly*\*\* in error. It is important to note also that the predictions were made in the *opposite direction* \*\*\*

---

From Department of Medical Psychology School of Aviation Medicine U. S. Air Force Randolph Air Force Base Tex

This refers to our report<sup>2, 3</sup>

Italics added by authors

These extreme statements are based on correlation coefficients reported in our paper. The error consists in that positive relationships were interpreted as negative as a result of misinterpretation of the tables. For example, we reported a correlation of .43 between psychologists' ratings of pilots made in the combat situation and psychologists' ratings of the same men in training. The combat scale, however, was oriented with high numbers representing superior adjustment and the training scale, in the opposite direction with low numbers representing the positive end. Because of the reversed scaling of these two variables, a minus sign of the correlation coefficient denotes a positive relationship. It thus appears that the critics overlooked or misread the definitions of variables, which were included in the tables.

In support of the same conclusion Sparks and Niess' statement on page 813 with reference to the accuracy of training level prediction "Interestingly enough the top jet ace of the study (n double ace) was a predicted failure. The four failures \* were all predicted successes."

Although prediction of psychiatric failures in combat had been rejected as a primary goal of our research in favor of the broader concept of adaptability, principally because they are the result of stress in the situation as well as individual personality limitations \* the files for the ace and the four failures were checked for the ratings of their adjustment in training (no predictions of combat performance were made). No data were available for one of the failures, who had been included in the follow up sample because he had taken an experimental test battery. Of the remaining four the ace had been rated moderately well adjusted and two of the three failures poorly adjusted. The fourth had made a satisfactory adjustment in training. Thus the combat records correspond to training adjustment for three of the four men for whom data were available—not five misses, as reported.

The statistics quoted by Sparks and Niess reflect numerous errors with reference to numbers of cases on which various correlation coefficients were based. Their table 1 (p. 814) indicates that 14 coefficients reported were based on 65 cases whereas the actual numbers ranged from 38 to 45 cases.

2. That psychologists in the combat zone presumably because of better understanding can predict combat adjustment accurately. Sparks and Niess state on page 814 "The fact that the combat psychologists' estimates agreed in general with peer superiors' estimates indicates a most essential need for investigators in this area to have a realistic understanding of combat, since training researchers tended to predict successes to fail and failures

---

\* This refers to 4 out of 111 pilots located in the follow-up sample who were found to be actual psychiatric failures in combat.

*to succeed. The results support the hypothesis that predictions of combat proficiency, based on psychiatric data adequately oriented to combat, can be made with sufficient precision to be of value in screening "\*\*\*\**

This claim represents a further misinterpretation of facts. After making correction of the minus signs, the correlation coefficient between psychologists' ratings in training and the mean of the ratings of pilots in combat by their fellow officers and superiors (peer superior ratings) was 0.32 (significant at the 0.05 level) while that between ratings by psychologists in the combat zone and the mean peer superior ratings in combat was 0.78. However, *only the training ratings could be treated as predictions made independently of the combat peer superior ratings.* The ratings made by the psychologists in the combat zone were made with complete knowledge of the peer superior ratings and differed from them only because additional data were taken into consideration. Under the circumstances, they cannot be compared as predictors with the training data.

The combat ratings were specifically designed to reflect as complete knowledge as possible of combat performance because they were being collected as criteria for the purpose of validating training ratings (used as intermediate criteria) and experimental screening tests. Captain Sparks was a member of the group sent to the combat zone for this purpose and collected these data in accordance with the above mentioned procedure.

There is no evidence available in our study concerning the comparative skill in prediction of combat performance from the very early vantage point of the training situation and subsequent observation in the combat zone. Our data do present convincing evidence that *prediction is feasible from early observation.* The correlation of 0.78 is primarily of interest to demonstrate the consistency of our adaptability ratings in combat with the opinions of other pilots.

3. That certain personality types are suited to particular combat assignments. Sparks and Niess state, on page 815, that "some men with obsessive compulsive personalities did very well in B 29's, but none were seen to do well in fighters, conversely, a number of those with 'psychopathic personalities' did splendidly in fighters but were not seen to do well in bombers."

Although this statement is not presented in quantitative terms, it may give support to individuals searching for an authoritative quotation to bolster a particular position. Our data, while not conclusive because of small numbers and the low magnitude of the relationships, tend to support the conclusion that well adjust

ed anxiety free, motivated co-operative, and conforming individuals make the best military pilots. While there is much latitude for exceptions scientific discipline requires that the general trends should be given weight while further study should be aimed at the exceptions.

In view of the importance of the issues discussed in this study, the reader is urged to read the complete published report.\* It is our belief that every writer should be entitled to the free expression of his opinions. However, when factual data are presented in support of opinion the accuracy and validity of these data are the measure of credibility.

#### WE WHO HAVE TAPE WORMS

The real editorial we refers to the annoying allusion to some nebulous and mysterious group of individuals in contact with the physician, when clearly he is working alone and has the prime responsibility for the patient. Could it be that a physician seeks to evade some responsibility for his patient through this device? Perhaps not but we wonder. Could not it seem appropriate in talking with patients to use other devices such as "It seems." It appears. I think. I believe. Mark Twain has been quoted as having said in effect "The editorial we traditionally and historically is reserved for the exclusive use of heads of state editors and people with tape worms. Anthelmintics—anyone?"

# COMPARISON OF NAVAL OFFENDERS WITH NONOFFENDERS ON A PROJECTIVE SENTENCE COMPLETION TEST

BERNARD LOCKE *Commander* USC USNR

**I**N A PREVIOUS series of articles, the author and his colleagues<sup>1-4</sup> demonstrated that naval offenders present a far greater incidence of psychopathology than do nonoffenders. It is the purpose of this article to explore, through the use of a projective sentence completion test, some of the specific, dynamic areas in which offenders differ from nonoffenders.

Fifty prisoners at the Third Naval District Brig were given the Stein Sentence Completion Test.<sup>5</sup> They were asked to complete each sentence with a word or a phrase as rapidly as they could, as a test of how quickly they could think. With similar instructions, the same test was given to an equal number of men who were part of the transient population of the U. S. Naval Receiving Station, Brooklyn, N. Y., and who had no history of any naval disciplinary difficulties. The two groups were matched in regard to age, education, and length of service.

The completed tests were coded, mixed, and then presented in turn to three experienced clinical psychologists, who were asked to rate them in accordance with the instructions on the rating sheet (fig. 1). The judges were not advised as to the nature of the two populations, or even that two populations were represented in the 100 cases they were evaluating. After a preliminary pilot study, which showed no significant differences between the judges, their ratings were pooled. The results of these evaluations are presented in table 1.

It is seen that in every area the prisoner group scored higher—indicating greater disturbance—than did the control group. In five of the areas and in the general clinical impression, these differences were statistically significant. The greatest discrepancy lay in the prisoner's self concept concerning his abilities. Here 21 of the prisoners were rated as "2," severely dis-

TABLE 1 Comparison of mean scores of prisoner and control groups

Element rated	Prisoners	Controls	D	D/PE diff
Attitude toward family unit	1.33	1.29	+ .04	.11
Attitude toward friends and acquaintances	1.21	.92	+ .29	1.71
Attitude toward superiors	1.50	1.38	+ .12	.86
Attitude toward inferiors	.87	.48	+ .39	3.00
Attitude toward peers	1.19	.80	+ .39	3.54
Fears	1.36	1.79	+ .07	.54
Guilt feelings	1.43	1.13	+ .30	3.33
Attitude toward own abilities	1.34	.91	+ .43	3.58
Attitude toward past	.84	.65	+ .19	1.73
Attitude toward future	.96	.70	+ .26	1.44
Energy level	1.18	.80	+ .38	2.38
General clinical impression	1.64	1.34	+ .30	2.50

Significant at the .01 level of confidence

Significant at the .05 level of confidence

turbed as compared to 11 of the control group. Fifteen of the control group showed no evidence of any difficulty in this sphere, as compared to only 6 prisoners who rated a score of "0."

In addition to the apparent low regard that the prisoner had for himself, he also had considerable difficulty in his relationships with his peers and with his inferiors. Twenty of the prisoners received a score of "2" regarding their relationships with their peers as compared to only 9 in the control group with a similar rating, indicating that the prisoner was more maladjusted in this sphere. Similarly, 13 of the prisoners were rated as being severely maladjusted in their relationships with their inferiors, as contrasted with 5 individuals in the control group who were so classed.

These findings can be interpreted as indicating that the popular concept of the offender as being a narcissistic, self-centered individual is far from correct. The prisoner's self-devaluation is borne out by his projection of his own feelings onto his peers and those he considers his inferiors, and by the extent to which his relationships with these he clearly considers his superiors are affected. Further evidence for this concept is presented by the fact that the prisoner group showed a much greater disturbance in the area of guilt feelings than did the nonprisoner group.

In considering the data presented in table 1, the question may be raised as to why it is that the control group scored high in at least four of the areas under consideration: attitude toward family unit, 1.29, attitude toward superiors, 1.38, fears, 1.29, and guilt feelings, 1.13, as well as in the general clinical impression 1.34. It is impossible to answer this question without adding a matched group from civilian life for comparative purposes. A logical hypothesis appears to be that since all the men who were tested had volunteered for duty in the Navy, it is possible that their difficulties with the family and authority figures, and the resultant guilt feelings, may have led them to attempt to escape from their difficulties in civil life through enlistment.

Following completion of the original ratings, the three judges were told the nature of the groups which they had rated, but not that the groups were equal in number. They then were asked to separate the test protocols of the prisoners from the nonprisoners. One judge was correct in 70 per cent of his choices, the second in 68 per cent, and the third in 60 per cent. Combining the three evaluations, we find that in about two thirds of the cases it is possible to differentiate the naval offender from the nonoffender.

#### SUMMARY AND CONCLUSIONS

Fifty brig inmates and a matched group of 50 men in nondisciplinary status were given the Stein Sentence Completion Test.

in order to tap differences in areas of conflict. Blind evaluation of the test results made independently, by three competent judges revealed that the prisoner group apparently was more maladjusted than the nonprisoner group in all areas studied, and showed that there were significant differences in attitude toward inferiors in attitude toward peers in guilt feelings, and in energy level. It is believed that the low esteem in which the average prisoner holds himself, and the resultant difficulties in interpersonal relationships, play an important part in the development of delinquent behavior in the Navy.

The data suggest the possibility, which should be evaluated, that men volunteer for military duty because of maladjustment in family relationships, difficulty with authority figures, and exaggerated feelings of guilt and fear.

It is possible for competent clinicians to separate prisoners from nonprisoners on the basis of a sentence completion test, with considerably better than chance success.

---

**ACKNOWLEDGMENT** The author wishes to express his thanks to Dr Elias A. Abrams, Dr Irving Handelsman, and Dr Selig Rosenberg for their assistance as judges.

## Duplication of the Small Intestine

## A Cause of Neonatal Intestinal Obstruction

PAUL A THOMAS, *Captain MC USA*  
 KENNETH B BOVILLA, *Captain MC, USA*  
 WARNER F BOWERS *Colonel MC USA*

**D**UPLICATION of the gastrointestinal tract is an infrequent entity, as judged from the number of recorded cases.<sup>1,2</sup>

As an etiologic cause of intestinal obstruction in the newborn infant, this congenital anomaly is rarely encountered, the majority of cases are the result of atresia, stenosis, or malrotation.<sup>3,4</sup> For the treatment of a patient with neonatal intestinal obstruction requiring surgical correction, a specific etiologic diagnosis is desirable when such is obtainable. The presence of a palpable, freely movable, cystic abdominal mass at birth, with symptoms of intestinal obstruction, is presumptive evidence of a duplication of the bowel as the underlying cause. Two patients recently treated at this hospital illustrate the above combination of circumstances which led to a correct pre-operative diagnostic impression. The second case is of further interest because of the associated volvulus of the duplication segment and complete 2 mm atresia encountered at the proximal end of the lesion.

Duplications of the alimentary tract have been described in the literature under a variety of names: enteric cyst, enterogenous cyst, ileum or jejunum duplex, and giant diverticulum.<sup>1,5</sup> These lesions have been reported to occur along the entire course of the alimentary tract from the tongue to the rectum.<sup>6</sup> This entity, however, has been most commonly observed in the small intestine.<sup>1</sup> Usually symptoms appear in infancy or childhood, although occasionally the lesion does not become symptomatic until later in adult life.<sup>2,7</sup> The symptoms most frequently observed are those of partial or complete intestinal obstruction. Rarely is the symptomatology of sufficient severity to attract attention in the first week of life. The youngest patient in the series reported by Ladd and Gross<sup>8</sup> was 2 weeks of age. In Kirtley and Matuska's<sup>9</sup> tabulation of all reported cases of enterogenous cyst of the duodenum, none was clinically evident with-

in the first week of life. In a review of acute abdominal conditions occurring in infancy, Norris and Braxton<sup>3</sup> did not list duplication as a cause of intestinal obstruction. Wilson,<sup>4</sup> on the other hand, encountered three newborn infants with obstructing duplications in a series of 57 who were operated on for congenital abdominal lesions. In two instances a duplication of the small intestine was associated with volvulus about the involved segment. In one of these a proximal atresia was described, similar in nature to the pathologic findings of the second case herein reported.

### CASE REPORTS

**Case 1** This baby girl was born 29 April 1956 after an uncomplicated gestation and delivery. Physical examination at that time revealed a freely movable cystic mass 2.5 cm in diameter palpable in the right lower abdomen. During the first several days of life, the infant had two dark-green stools. By the fourth day, however, persistent vomiting after each feeding was observed. Physical examination at this time confirmed the presence of an abdominal mass; the abdomen also was slightly distended and bowel sounds were high pitched. A roentgenogram of the abdomen (fig. 1) was consistent with early mechanical intestinal obstruction.

On the fifth day of life the infant was operated upon for an obstructing duplication cyst of the ileocecal valve (fig. 2). The lesion presented on the inferolateral aspect of the distal ileum and cecum away from the mesentery. The cyst was incised to aspirate about 30 ml of clear yellow fluid and relieve the extrinsic pressure obstruction of the ileum. The cyst wall was then partially excised, leaving the contiguous wall along the ileum and cecum undisturbed. Postoperatively the patient recovered without incident and when last seen at several months of age was doing well. Pathologically, the wall of the cyst, smooth muscle, was lined by colonic type mucosa.

**Case 2** This baby boy was born 1 July 1957 after an uncomplicated gestation and delivery. Physical examination at that time revealed a 4 by 6-cm freely movable, cystic mass palpable in the left lower abdomen. An unusually large amount (125 ml) of gastric content was aspirated by catheter. For several days the infant appeared to do well and two small dark-green stools were passed. By the fourth day persistent gastric retention and vomiting were observed. Physical examination at this time confirmed the presence of an abdominal mass which transilluminated light. Bowel sounds were present but markedly decreased on auscultation. Deepening jaundice also was noted but considered physiologic. Microscopic examination of meconium did not show the presence of any desquamated cells or debris. A roentgenogram of the abdomen (fig. 3) was consistent with a mechanical intestinal obstruction. On the fourth day of life the infant was operated upon for an obstructing duplication of the jejunum (fig. 4). A volvulus

*Figure 1 (case 1) Preoperative roentgenogram revealing moderate gaseous distension of the stomach and small intestine compatible with early intestinal obstruction*

*Figure 2 (case 1) The exposed ileocecal region at operation. The duplication cyst is evident on the antimesenteric aspect with the appendix lying on the surface. The proximal ileum is moderately dilated.*

of the involved segment was reduced and on further inspection a 2 mm fibrous atresia was observed at the proximal base of the pathologic segment. Resection of the jejunum to include the duplication and atresic bowel with end-to-end anastomosis was performed. The postoperative recovery was complicated by a superficial wound breakdown which was allowed to heal by secondary intention. The baby is presently doing well. Pathologically the wall of the cyst smooth muscle, was lined by small intestinal type mucosa.

#### DISCUSSION

The gross pathologic characteristics of these lesions have determined the various corrective surgical measures employed in the past. The intimate association of the smooth muscle wall of the contiguous normal channel with that of the enteric cyst makes simple enucleation extremely hazardous. Frequently the lesion is situated between the leaves of the mesentery, with the vascular supply to the normal bowel coursing over the cystic mass. This further complicates any attempt at enucleation. Therefore, the ideal surgical treatment is extirpation by resection of the involved segment and reestablishment of intestinal continuity by anastomosis. Where resection has not been technically feasible, marsupialization of the cyst, either into the gastrointestinal tract or to the exterior, has been accomplished with satisfactory results.

*Figure 3 (case 2) Preoperative roentgenogram revealing moderate gaseous distension of the stomach duodenum and proximal jejunum compatible with complete intestinal obstruction*

The first case was unusual in that the duplication was anti-mesenteric and did not involve the blood supply to the normal bowel. Therefore, it was treated by partial excision of the duplication, leaving the area of contiguous attachment between the cyst and normal bowel undisturbed. The narrow strip of mucosa exposed to the peritoneal cavity was not cauterized or otherwise treated. This decision is justified on the basis that experimentally various intestinal segments have been isolated and turned inside out in the peritoneal cavity to absorb excessively produced fluid, as in ascites, without harmful effect.<sup>6</sup> This infant did well following surgery.

The second patient, on the other hand, exhibited the more characteristic finding of a duplication cyst presenting between the leaves of the mesentery. In this instance the mesentery was sufficiently redundant to allow a volvulus of the pathologic

*Figure 4 (case 2) The exposed jejunum at operation. The duplication cyst is evident between the leaves of the mesentery with the blood vessels coursing over the surface. The collapsed jejunum is noted over the outer aspect of the cyst.*

segment to occur. The presence of a concomitant atresia was interesting. In retrospect the high level, complete intestinal obstruction was responsible for the unusually large volume of gastric aspirate obtained at birth.

#### SUMMARY

Two cases of duplication of the small intestine with signs and symptoms of intestinal obstruction within the first week of life are reported. The presence of a palpable, freely movable, cystic abdominal mass at birth is presumptive evidence of a duplication cyst of the gastrointestinal tract. The first case was unusual in that the ileocecal duplication presented on the antimesenteric aspect of the bowel. This circumstance is favorable for a simple, partial excision of the cyst wall without disturbing continuity of the normal intestinal tract. Such was the treatment in this patient. The second case was complicated by the surgical observation of volvulus of the involved segment as well as a concomitant atresia of the jejunum at the base of the duplication. In the majority of infants with gastrointestinal

duplication surgery may be deferred until a time of election, however, in the presence of intestinal obstruction, as observed in these two newborn infants, surgical correction becomes urgent

## ARE YOU READY FOR SPACE TRAVEL?

Science fiction has provided us with extraordinary ideas about the physiology of space man but in the United States many individual scientists, government agencies and private organizations are studying the problems which man will have to contend with if and when he leaves the earth for outer space or even tries to fly at very great heights and very great speeds. It has been claimed by one physiologist that man will be ready for space travel as soon as space ships are ready and that this will be sooner than most people suspect. This seems an overoptimistic view but the investigations to determine whether it is possible are being carried out in the United States with increasing tempo.

### MEDICAL OFFICERS RECEIVE AWARDS AT ANNUAL MEETING OF MILITARY SURGEONS

Medical officers of the military services shown on these pages received the highest scientific awards at the 64th annual meeting of the Association of Military Surgeons held in Washington D C 28 30 October under the presidency of Colonel Amos R Koonitz MC Maryland National Guard

Shown above are most of the seventy four officers from other countries who attended the meeting. Colonel Koonitz is in the center of the first row. On his left is Major General Paul I Robinson MC USA Executive Director of the Dependents Medical Care Program. Colonel George B Green USAF (MC) was chairman of the Foreign Liaison Committee.

Colonel Charles R. Mueller MC USA (retired) above Director of Medical Service Department of Medicine and Surgery Veterans Administration was installed as president of the Association at the close of the 1957 meeting.

Brigadier General Carl W. Tempel MC USA left Commanding Officer of Valley Forge Army Hospital was the winner of the Stitt Award for merit to 1957 achievement in the use of antibiotics in the treatment of tuberculosis. He was given the award by Dr Jerome J. Van Gasse General Manager of Pfizer Laboratories Division, Charles Pfizer & Co. Inc.

Assistant Secretary of Defense Dr. Frank B. Berry right was the moderator of a panel on "Medical Education in the Federal Services" which included Dr. John C. Hunemaker Veterans Administration Dr. James A. Shannon Director National Institutes of Health Rear Admiral B. W. Hogan Surgeon General of the Navy Dr. Leroy E. Burney Surgeon General of the Public Health Service Major General Silas B. Hays Surgeon General of the Army Major General Dan C. Ogle Surgeon General of the Air Force

Colonel John P. Sharp USAF (MC) right is shown receiving the Gorgas Medal from Mr. Herbert W. Blades President of Wyeth Laboratories sponsor of the award. The medal was given for outstanding contributions to preventive medicine through deceleration studies

Major General Paul I. Robinson MC USA left general chairman of the 64th annual meeting of the Association receives the Founder's Medal from Colonel Koontz.

Captain William W. Ayres MC USN Armed Forces Institute of Pathology won the Sir Henry Wellcome Medal and Prize

## DR DEARING NAMED HEALTH DIRECTOR IN OFFICE OF DEFENSE MOBILIZATION

Dr. W. Palmer Dearing, formerly Deputy Surgeon General of the U. S. Public Health Service, has been appointed to the newly created position of Assistant Director for Health in the Office of Defense Mobilization Executive Office of the President by Gordon Gray, Director of Defense Mobilization. Mr. Gray formerly was Secretary of the Army and later Assistant Secretary of Defense for international security affairs.

*Dr. W. Palmer Dearing*

Dr. Dearing, a *cum laude* graduate of Harvard Medical School in 1931 and of the Harvard School of Public Health, has been a Public Health Service career officer since 1934. He served as an epidemiologist in studies of poliomyelitis in California from 1934 to 1936 and tuberculosis from 1936 to 1941. In 1941 he was assigned to the Office of Civilian Defense as assistant and subsequently chief medical officer. In 1944 he was named personnel chief of the health division, United Nations Relief and Rehabilitation Administration. He returned to Public Health Service headquarters in 1945 as Deputy Chief of the Division of Public Health Methods

and a year later was named Chief of the Division of Commissioned Officers, in which post he undertook a complete overhauling of policies for recruitment, training, and assignment of officers.

Named the Deputy Surgeon General of the Public Health Service in May 1948, Dr. Dearing was the third officer to hold that position since the creation of the position by the 76th Congress in 1939. He is a native of Palo, Iowa, but received his early schooling in California and Washington, graduating from Washington State College in 1927. He was a member of the founder's group of the American Board of Preventive Medicine, a fellow of the American Public Health Association, and a former member of the House of Delegates of the American Medical Association.

## A MESSAGE FROM THE A

In 1956 the Secretary of Defense gave active the elimination of the Veterinary Corps in the Army. More recently, by administrative action Secretary Wilson informed the Secretaries of the Air Force that inspection and grading services for subsistence items of animal origin in the United States and Hawaii were to be transferred to the Department of Agriculture as promptly as is mutually agreeable to the Army and the Secretary of Agriculture. Similar work in connection with food borne diseases is to be transferred to the Department of Agriculture.

With the transfer of inspection and grading services for subsistence items and laboratory work in connection with food borne diseases and animal diseases, the Secretary of the Army was given 60 days in which to negotiate and approve an agreement with the Secretary of Agriculture for performance of those functions. In addition, the Army and Air Force are to develop plans and test the performance of depot, post, camp, and station inspection activities by the Department of Agriculture.

In support of the action, the Secretary of Defense indicated that it is in the overall interest of the Government for his Department to utilize the extensive and specialized resources of the Department of Agriculture in the subsistence inspection area. At the time the directive was issued, the Department of Agriculture already was performing one third of the inspection functions for the Department of Defense. The Secretary said that his action would eliminate divided responsibility and centralize the entire function in the Department of Agriculture by transferring the remaining two thirds. It is estimated that such action will result in a saving of 100 officer spaces and 500 enlisted spaces.

Orderly and equitable disposition of veterinary personnel, under the terms of the directive, is to be made by release from active duty, transfer, or reassignment. Commissioning and activating reserve veterinary personnel after 1 October 1957 is not authorized except where necessary in the judgment of the Secretaries of the Army and Air Force to prevent inequities.

In a report to the Board of Trustees in May 1956, the Council on National Defense pointed out that the Congress legislated to

From the Council on National Defense of the American Medical Association. The views and opinions expressed are not necessarily those of the Department of Defense.  
—Editor

establish the Army Veterinary Corps in the National Defense Act of 3 June 1916 and reaffirmed its action in the Army Organization Act of 1950. Further, the United States Air Force recognized the military necessity for a veterinary service and administratively established a Veterinary Corps in 1949.

The Council recommended that the American Medical Association vigorously oppose any action by the Department of Defense that would reassign, discontinue, or obtain through contractual arrangement the various functions performed by the Army and Air Force Veterinary Corps. In recommending this action, the Council recognized that military veterinarians have made and continue to make valuable contributions to medical science of both military and civilian significance. Military veterinarians have played a vital role in successfully protecting military personnel from food borne and animal diseases throughout two world wars and the Korean conflict, and have been responsible for inspection of food used by the Armed Forces.

The professional capabilities, military training, and centralized control of the Army and Air Force Veterinary Corps have established them as indispensable components of the over all preventive medicine program and as important paramedical elements in the event of atomic disaster. The officers of this corps, trained and being trained in radiobiology, radiotoxicity, and radioassay as these pertain to foodstuffs and food producing animals subjected to the effects of nuclear detonation, comprise a group whose technical knowledge and capabilities will be of inestimable value to both military and civilian populations in the event of atomic disaster. Such a group would be difficult of replacement.

Officers of the Army and Air Force Veterinary Corps, having been trained in the medical care of human casualties, should be relied upon to assist medical officers in the event of atomic disaster. The elimination of military veterinarians will substantially increase the Armed Forces requirements for medical officers to assume many of the functions performed by the veterinarians, thereby reducing the number of physicians available for the medical care of the civilian population.

For these reasons, the House of Delegates of the Association, in June 1956, voted to oppose the elimination of military veterinarians.

On 16 October 1957, the Association sent a letter to Secretary of Defense Neil H. McElroy outlining the action previously taken by the medical profession on this subject and requesting that in light of the responsibilities of the Secretary of Defense for the health of the personnel of the Armed Forces under their world wide missions at world wide bases he carefully reconsider the 1 October directive, which in effect abolishes the military Veterinary Corps.

## PHONOGRAPH RECORDS AID TEACHING

The Indiana University School of Dentistry and the University of Pennsylvania School of Dentistry for the first time in any dental school as far as it is known are making available to their students and faculty a new technic in dental education. Outstanding clinicians of the country are brought to the classroom and library where a "clinics on record" collection is established. These records are available to the practicing

*Dr. Maynard A. Hine, Dean of Indiana University School of Dentistry, center; Dr. Ralph E. McDonald, Chairman of the Department of Dentistry for Children, seated; and Dr. Arthur Klein, a member of the children's department faculty, listening to Dr. McDonald's "clinics on record" in the library of the dental school.*

dentist in his home through the medium of his phonograph. "Clinics on record" makes distance from clinical instruction centers no longer a barrier to learning new techniques. Not intended to replace clinical participation but to supplement it, the method should prove helpful to many dentists who find it impossible to attend every clinic they should attend.

## CORRESPONDENCE

### Tuberculosis of the Liver

*To the Editor* —In my opinion the abstract "Primary Military Tuberculosis of the Liver" on page 1,357 of the *U S Armed Forces Medical Journal* for September 1957, should not have been published. This is an abstract of an article by the same title by Terry and Gunnar published in the *Journal of the American Medical Association* of May 11 1957. To any pathologist the concept of primary military tuberculosis of the liver is untenable. Terry and Gunnar in their original article freely admit that "Primary tuberculosis of the liver" is inaccurate because the condition is invariably secondary to tuberculosis elsewhere. As a matter of fact they devote half a page in the *J A M A* to an apology for and an explanation of what they mean by the term. They admit that they use it for reasons of convenience. In my opinion their arguments in favor of the title are weak and indefensible. The abstract published in your Journal gives no inkling of this and therefore it is misleading.

JOHN H. SCHAEFER M D  
525 South Flower Street  
Los Angeles 17 Calif

*The above letter from Doctor Schaefer was sent to Doctors Terry and Gunnar who made the following comment:*

*To the Editor* —Although we are more interested in the diagnosis and cure of primary military tuberculosis of the liver than in its pathology or semantics we sympathize with Doctor Schaefer distress at our use of the words "primary" and "tuberculosis" in the title of our article for he is a pathologist and so a pathologist (as so ourselves) primary tuberculosis can only mean one thing. We thought however that we had made it clear that "primary" referred to "military" rather than to tuberculosis and that "primary military tuberculosis of the liver" was therefore justified. We should also like to point out that no matter what name is used it is necessary to recognize military tuberculosis confined to the liver as an important cause of fever of undetermined origin which is readily diagnosed by needle biopsy of the liver and gratifyingly responsive to treatment with isonicotinic acid hydrazide—but diagnosis and cure are both unlikely unless this rather occult situation is kept in mind.

### Dental Water Turbine Handpiece

To the Editor—We have received a copy of the September 1957 edition of the *United States Armed Forces Medical Journal*. Please be advised that there is an error in the article by Commander Frank J. Brauer titled "Increasing Dental Speeds" starting on page 1291. On page 1292 under "Water Turbine Handpieces" there appears a statement as follows: "A water turbine (hydraulic) handpiece developed at the University of Michigan operates at about 60,000 r.p.m. The water turbine (hydraulic) handpiece was developed by Dr. R. J. Nelson, Mr. C. E. Pelander and Mr. J. W. Kumpula at the Dental Research Section, National Bureau of Standards and not at the University of Michigan as stated. Reference to the article cited by Commander Brauer will show that the handpiece developed at Michigan was air driven and not water driven. Your assistance in clarifying this matter will be appreciated.

National Bureau of Standards  
Washington 25 D C

Mr. Stanford's letter was referred to Commander Brauer who replied as follows:

To the Editor—I find that I erroneously listed the air turbine handpiece developed at the University of Michigan as a water turbine instrument. Proper due credit for the water-turbine instrument with the turbine in the head of the instrument belongs to the Research Section, National Bureau of Standards. Thank you for your kind attention to this matter.

FRANK J. BRAUER, Commander, DC, USN  
U S Naval Station  
Navy No 27  
c/o Postmaster Seattle Wash

### Dental Courses Announced

A five day dentistry work shop will be conducted by the Sterling Rock Falls Rehabilitation Center in Rock Falls, Ill. 26-30 January 1958 immediately preceding the mid winter meeting of the Chicago Dental Society. The course will cover prosthetic restorations of the ear, nose and parts of the face using both hard and flexible prostheses. During the month of August 1958 another course will be offered in the theory and technique of maxillofacial surgical, orbital and cleft palate care. Additional information may be obtained from Edwin N. Cooper, Executive Director, Sterling Rock Falls Rehabilitation Center, 303 W. 2nd Street, Rock Falls, Ill.
